The treatment of salpingo-oöphoritis should in the first place always be palliative. The infected cervix is first dealt with, and thereafter the diseased appendages are treated by rest, attention to the bowels to relieve pelvic congestion and local pressure, douching, and plugging with some such material as ichthyol in glycerin. A mixed vaccine containing streptococcus and *B. coli*, given in doses below the reaction point and administered over a period of several months, is often useful. Under such measures clinical recovery may sometimes be looked for, although functional recovery with an opening up of blocked tubes is much less certain. Where the local or the general symptoms persist operative removal of the diseased appendages is called for.

Sterility.—In many cases of chronic infection of the genital organs the consideration of greatest moment to the patient and her husband concerns the possibility of further pregnancies. The doctor is often asked to give an opinion on the prospects, and in any treatment to be carried out the chance of conception which this will give often weighs largely with the patient. At the outset we have to remember that it is always necessary to give a very guarded prognosis, because experience teaches that a period of sterility following chronic infection frequently implies a permanent loss of function. At the same time the outlook must necessarily depend on the degree and site of the damage. Thus, in that most common infective lesion chronic cervicitis, which is a common cause of sterility, pregnancy not infrequently follows active local treatment. The reposition of a retroflexed uterus, and its suspension with a vaginal pessary, is also sometimes followed by pregnancy. The outlook is gloomiest in cases of tubal infection, for whilst it is true that chronically infected and blocked tubes may become spontaneously recanalized, as witness the occurrence of tubal pregnancy in such cases after a period of sterility, in the majority of instances the fine structure of the tube is damaged beyond repair. In some cases an abdominal operation for the purpose of liberating the adherent tubes and ovaries and the making of a new ostium in closed tubes (salpingostomy) may be followed by pregnancy. Where, on the other hand, the destruction of tissue is great, the chances of functional recovery are negative, and such operations as that which consists in insinuating the ovary with its mesentery into the uterine cavity through a hole made in the cornu are still too untried to be generally justifiable. It should be mentioned that, short of operation, a certain amount of accurate information regarding the condition of the tubes can be obtained by two methods recently added to our diagnostic procedures—namely, the insufflation of the tubes from the uterus by means of air or carbon dioxide under pressure, and the injection of some opaque fluid (for example, lipiodol) into the tubes via the uterus, followed by an x-ray photograph. By these methods the existence and the site of a tubal block can be recognized, and pregnancy practice is sometimes followed by pregnancy, probably owing to the gas or fluids having dislodged some obstructing discharges lying in the tubes.

Finally, we have to remember that infection of the pelvic organs must always be considered in our hunt for sources of focal sepsis in cases of chronic rheumatism, chronic heart disease, etc. The two following cases illustrate this point.

1. A 3-para, aged 37, had suffered from chronic ill health since childbirth nine years previously. Of the last two years she had spent eighteen months in hospital for valvular heart disease and progressive rheumatoid arthritis with marked deformity of wrists, elbows, ankles, and knees. Leucorrhœa was discovered on the last occasion in hospital. The cervix was found to be very septic and was amputated. This was followed by rapid improvement in the condition of the joints and in general health.

2. A primipara, aged 34, with a progressive painful rheumatoid condition of the wrists, fingers, and ankles of several years' duration. Leucorrhœa was present, together with a "granular" vaginitis secondary to infection of the cervix and uterine body. Panhysterectomy was performed. Within a few days improvement set in and increased progressively thereafter. Within two months the vaginitis and leucorrhœa were arrested and the swelling and tenderness of the joints gone. Movement and use of the limbs were being recovered fairly rapidly.

General Causes of Ill Health.

The conditions previously brought under review in this address, although entirely local in their origin and often predominantly local in their symptomatology, may initiate a pathology which spreads its ravages beyond the pelvis to almost any system and region. Thus we have seen that prolapse frequently causes gastric and intestinal dyspepsia, involvement of the urinary tract, and nervous phenomena, and the same is also markedly true of chronic pelvic infection. In the majority of cases of pelvic infection we find irritability of the bladder with diurnal and often nocturnal frequency. There may be an associated bacteriuria and pyuria, although not uncommonly the urine is free of abnormal constituents. Whether this involvement of the urinary tract is due to a direct spread of the inflammation across the tissues intervening between the infected area—for example, the cervix, and the bladder and ureter—or whether it is a blood-borne infection it is difficult to say. Furthermore, chronic pelvic infection may constitute the causal factor in cases of rheumatism and heart disease, whilst both puerperal sepsis and the toxæmias may produce brain lesions that persist in the form of mental impairment or even actual insanity. We have, further, to remember that there are a variety of antecedent diseases, such as gonorrhœa, pulmonary phthisis, heart disease, and Bright's disease, which are specially liable to suffer exacerbation by the fact of pregnancy or the strain of labour, whilst there is hereby any taint which is not apt to be augmented by an abnormal pregnancy or the debility following a complicated labour which saps the general resisting powers of the patient.

A class of disease often with obscure symptomatology but with pointers towards an origin in an *endocrinal abnormality* is not an uncommon legacy from pregnancy and childbirth. Space will allow of only a brief reference to this extremely interesting and at the same time intriguing type of disorder, which constitutes a field in which further data remain to be gathered. A common complex includes amongst its salient features an increasing general adiposity, dryness of the skin, thinning and falling out of the hair, scantiness, suppression, or irregularity of the menses, and a low basal metabolic rate—features, in other words, suggestive of a hypothyroidism, with perhaps a superadded ovarian deficiency. In other cases the appearances are more suggestive of a pituitary syndrome. Many of these patients have obvious pelvic lesions, and it is not improbable that the endocrinal upset is usually secondary to pelvic sepsis. Hence it is necessary to treat the focal factors in addition to the exhibition of the appropriate

land products (ovarian, thyroid, pituitary). The follow-ig case may be quoted in illustration of these conditions.

A *primipara*, aged 28, since the birth of a child two years reviously, which was nursed for seven months, had never felt ell. There was complete amenorrhoea, and she complained of ucorrhoea. She gained nearly 3 st. in weight. The skin was cy, and the hair falling out. On examination she was found have marked cervical infection; otherwise there was nothing normal in the pelvis. The cervix was treated, and half a grain thyroid extract *administered night and morning*. *Within two* ionths the weight was reduced by 1 st. and menstruation sumed.

A still further cause of loss of health following child-earing is found in the dregs remaining behind after regnancy pyelitis and toxaemia. In the production of yelitis, stasis in the ureter due to the pregnant state is n important predisposing cause, and there is usually a apid recovery from the symptoms after delivery, but, on ccasion, active infection of the urinary tract may remain, ausing pain and tenderness in the kidney area and bdomen, frequency of micturition and dysuria, recurring yrexia, and pyuria. In some cases the condition first eveals itself in the puerperium. It is important in all uch cases to make a careful search for areas of focal epsis, as this factor is known to play an important part n the initiation and perpetuation of infection of the urinary tract. Another lesion of the urinary tract, o which Hunner has recently directed special atten-ion, is *stricture of the lower end of the ureter* with lilatation of its upper section and of the renal pelvis. Whilst predisposed to by child-bearing, it occurs not in-requently in childless women. In some cases it is asso-iated with infection. Its chief symptoms are backache igh up in the flanks, pain and tenderness over the corre-ponding side of the abdomen, and frequency and pain on nicturition. The urine may be normal, or may reveal nothing but an occasional red blood cell or leucocyte. The ain, especially at first, may be definitely menstrual in its iming, and if situated, as it commonly is, in the iliac egion, it may suggest a gynaecological source. In other ases the occurrence of nausea and sickness may lead to an rroneous diagnosis of appendix, gastro-intestinal, or gall-bladder disease. Such errors may lead to faulty treatment *and to futile operations. In other cases the stricture* of the ureter is combined with gynaecological or other disease. The condition is revealed by the existence of an obstruction to the passage of a bougie and by a pyelographic examination following the injection of an opaque fluid. The treatment consists in dilatation of the stricture in one or both ureters by means of a bulbous ureteral bougie. At the same time any local pelvic lesion that may be contributing to its production—for example, cervicitis or cellulitis—should be dealt with. According to Hunner a not uncommon causal factor is focal sepsis in the teeth or tonsils, and this, if found, must receive attention.

Pregnancy toxaemia, like pyelitis, is usually recovered from quickly after the birth of the child. In some cases, however, especially in women who have had a recurrent series of toxic pregnancies, the acute kidney lesion may pass over into chronic kidney disease. In such women *chronic cardio-vascular lesions*, as manifested by persisting hypertension, arterio-sclerosis, and hypertrophy and dilatation of the heart, are commonly present as well. In a recent communication[1] I have shown that in about 50 per cent. of cases pregnancy toxaemia (eclampsia, albuminuria) recurs in succeeding gestations, and that in women with this taint the risk of permanent *cardio-renal lesions* increases with each succeeding pregnancy. For this reason women who have had two toxic pregnancies should be instructed to avoid further pregnancies, whilst, in the event of conception again occurring, they must become the subject of very strict ante-natal supervision.

I must not take leave of our subject without a reference to the influence of child-bearing on *gall-bladder disease*, which constitutes a fertile source of chronic invalidism in women, especially in the middle and later periods of life. It is well known that gall-stones are two or three times commoner in women than in men, and that the main factor behind this high female incidence is multiparity. In attempting to explain the bearing of pregnancy on this tendency to cholelithiasis we have three possible factors to consider, which may operate singly or in combination. The first is the high cholesterin content of the blood in pregnancy, and which in the last months is about twice the normal (Moynihan).[2] The second is the tendency to the occurrence of stasis in the biliary ducts during pregnancy. The third is the frequency with which women who have borne children suffer from focal sepsis in the pelvic, urinary, and, other regions. There is reason for the belief that infection of the gall-bladder usually precedes the deposition of stones, and that this infection may reach the gall-bladder from some such distant source. Gall-bladder disease is notorious for the frequent obscurity of its symptomatology. Where it is associated with local pain and tenderness, recurring biliary colic, and jaundice its recognition is easy. Often, however, these cardinal features are absent, and its presence will be missed unless it is brought under suspicion in all cases of parous women, especially those tending to obesity, who suffer from *chronic ill health*, dyspepsia, and vague abdominal symptoms. It is a common accompaniment of chronic gynaecological disease.

CONCLUSION.

The woman suffering from chronic ill health dating from *childbirth* is frequently the subject of multiple lesions. Failure to carry out a comprehensive investigation of the various systems may lead to an imperfect diagnosis, resulting in operations and other forms of treatment that bring little relief.

THE DIAGNOSTIC VALUE OF THE PLANTAR RESPONSE IN INSULIN COMA.

BY

P. M. D'ARCY HART, M.B., B.CH., M.R.C.P.,
MEDICAL REGISTRAR, ROYAL NORTHERN HOSPITAL;

AND

HILDA PRICE BOND, M.B., B.S., M.R.C.S., L.R.C.P.,
HOUSE-PHYSICIAN, ROYAL NORTHERN HOSPITAL.

RECORDS of the plantar reflexes in insulin hypoglycaemia are rare. Emmons[1] was apparently the first to report an extensor response in a case of insulin coma during the period preceding recovery. Elliott and Walshe,[2] in comment on Emmons's case, suggested that the state of the plantar reflexes might be of great value in distinguishing between ordinary diabetic coma and that due to hypoglycaemia, but they could not supply the necessary clinical evidence. Pemberton[3] then reported a fatal case of insulin coma, in which an extensor response was obtained, persisting up to within a few minutes of death. On the other hand, a flexor response was recorded by Graham[4] in a case of temporary hemiplegia without coma, the result of insulin overdosage.

In the two cases of insulin hypoglycaemia described in this paper an extensor response was observed while the patients were comatose. As consciousness returned the extensor response faded, the plantar reflexes becoming flexor in one case and inexcitable in the other.

It seems to us that these cases now suffice to provide the evidence required to establish the *clinical value of this* physical sign as a means of distinguishing between the two states of coma in diabetics.

CASE I.

The patient, a man aged 70, was admitted to the Royal Northern Hospital on November 24th, 1928, suffering from severe diabetes of at least three years' duration. Two years previously he had been taken to an infirmary in insulin coma, but there had been no recurrence of this complication.

On admission his general condition was good, in spite of loss of weight. The urine contained sugar and acetone bodies in considerable amount. He was given a generous diet with 10 units of insulin morning and evening. On November 27th the blood sugar three hours after insulin and breakfast was 0.24 per cent., and accordingly the dose of insulin was increased.

At 11.30 a.m. on December 2nd the patient rose as usual for his bath, but on getting out of bed felt giddy, and fell against his locker. He was put back to bed. At 12.40 p.m. he collapsed, *becoming breathless, cold, and clammy*. He was able, however, to drink 7 ounces of 5 per cent. glucose, while 10 minims of

adrenaline 1 in 1,000 were given intramuscularly. In spite of these measures he passed, half an hour later (1.10 p.m.), without fits, into a state of complete coma. The pulse was slow and irregular, and the breathing stertorous. No acetone could be detected in the breath. The pupils reacted to light, and were not dilated. The knee-jerks were brisk, and the plantar response of both feet was definitely extensor. A catheter was passed, and the urine found to be free of sugar.

He was given 50 c.cm. of 25 per cent. glucose intravenously. This led to rapid recovery, the patient changing in five minutes from a condition of coma to complete consciousness and intelligence. Examined half an hour later the plantar reflexes were equivocal, the definite extensor response being no longer obtained.

During the night of December 4th the patient had a second attack of insulin coma. As before, this was heralded by shivering and a feeling of coldness. He was easily revived by rectal glucose, followed by a drink of tea with sugar.

Examined on December 14th, the knee-jerks were brisk, ankle-jerks slight, and the plantar response was absent in both feet.

No further attempt to lower the blood sugar to the accepted normal value was deemed advisable at this stage, and the patient was discharged on December 18th with instructions to attend the out-patient department. The dose of insulin was then 15 units morning and evening. This was increased later, and when last examined on February 6th, 1929, he was taking 25 units morning and evening; the blood sugar was 0.16 per cent., and the urine was sugar-free.

CASE II.

The patient, a woman aged 66, was admitted to University College Hospital on February 20th, 1929, suffering from severe diabetes. Emaciation was extreme, her weight being only 4½ st., and the urine contained a large amount of sugar and acetone bodies. The knee-jerks were absent and the plantar reflexes flexor. She was given a diet of 1,000 calories with 20 units of insulin twice daily. With this dosage of insulin the glycosuria persisted, and the blood sugar was 0.23 per cent.; in consequence the dose was increased, together with the diet, until she was taking 100 units a day on a diet of 1,500 calories. The urine then became sugar-free.

Shortly after midnight on March 5th the patient had what appeared to be a hypoglycaemic attack. It lasted twenty-five minutes, during which she was unconscious and restless, throwing her limbs about, and foaming at the mouth. The pupils were inactive to light, and there was incontinence of urine and faeces. The condition was relieved by adrenaline and glucose.

The next day, at 1.45 p.m., the patient was noticed to be flushed, restless, and confused. Glucose was given by the mouth, but in spite of this she became more and more drowsy, and when examined at 3 p.m. was completely comatose, the swallowing reflex, however, remaining. Slight stiffening of both arms was noted, but no convulsions were observed. The left plantar reflex was definitely extensor, the right being doubtful on account of the deformity of hallux valgus.

Blood was taken for the estimation of sugar, which was found to be 0.05 per cent.; meantime the oral administration of glucose was continued, but in increased amount. During the succeeding half-hour consciousness returned, at first gradually, and then with rapid awakening; when examined at 3.45 p.m. she was completely conscious, and the plantar response was flexor in both feet.

A fortnight later, on examination, the knee-jerks were sluggish, ankle-jerks absent, and both plantar reflexes were flexor.

There was no arterial obstruction in the circulation through the feet in this case.

There is thus a certain amount of evidence to show that insulin hypoglycaemia, if severe enough to produce coma, is likely to be accompanied by an extensor plantar response during the stage of unconsciousness. In exhibiting this phenomenon insulin hypoglycaemia resembles a variety of other toxic states associated with coma, including cholaemia, eclampsia, and uraemia. While, however, in the latter two conditions epileptiform fits seem to be essential for the appearance of an extensor response (Elliott and Walshe[2]), this does not hold in insulin coma, for in Case i no convulsions were observed at any stage.

The character of the plantar reflexes in insulin coma is in striking contrast to that obtaining in ordinary diabetic coma, in which condition, unless there is some other associated organic disease affecting the pyramidal tract, an extensor response apparently never occurs. Allen and his co-workers[5] give a detailed description of 17 cases of diabetic coma. They frequently found the tendon-jerks diminished or absent, but noted no other abnormality of the reflexes. Elliott and Walshe[2] failed to obtain an extensor plantar response in any of the cases observed by them, even after two days of coma, and within an hour of death. In examining the records of 53 cases of diabetic coma of all degrees of severity we have not found an extensor response noted, except in one instance; this was a patient in whom coma had been precipitated by a cerebral abscess. A flexor response was definitely recorded in 21 of the other cases.

It is suggested, therefore, that the state of the plantar reflexes may prove to be of great assistance in quickly distinguishing ordinary diabetic coma from that due to insulin hypoglycaemia. Mild hypoglycaemic attacks without coma are not accompanied by an extensor response, and it is possible that even deep insulin coma may not show the extensor phenomenon. But inasmuch as diabetic coma, unless complicated by an organic pyramidal tract lesion, does not give an extensor response, it is plain that the occurrence of this physical sign in a comatose diabetic on insulin treatment should be accepted as evidence that the coma is due to excess of insulin, and consequently sugar (intravenous 10 per cent. by preference), together with subcutaneous adrenaline, should at once be given very freely. The state is dangerous when once an extensor response has appeared, and there is little time to be lost. The quick recovery of the patient, upon adequate treatment with sugar, is totally unlike the very slow emergence from diabetic coma.

We wish to express our thanks to Dr. E. G. B. Calvert and Professor T. R. Elliott for permission to publish these cases of insulin coma, and to the physicians of the Royal Northern Hospital, St. Mary's Hospital, and University College Hospital, who have allowed us to use the records of their cases of diabetic coma for comparison.

GROWTH RECOVERY AFTER INHIBITION BY LEAD.

BY

FREDERICK S. HAMMETT.

(The Research Institute of the Lankenau Hospital, Philadelphia.)

IN previous papers of this series (Studies in the Biology of Metals) results were reported demonstrating that growth in length of roots is retarded by Pb-ion,[1] and that this is due to inhibition of cell division.[2] These findings as they stand seem good evidence in favour of the lead treatment of malignant growths,[3] particularly in view of the fact that the regions of most active growth by increase in cell number in the chick embryo are similarly affected.[4] But the whole story is not told until we know what happens when the growing organisms are removed from the Pb environment. With this in mind I have first inhibited growth of roots of yellow corn (*Zea mays*) seedlings for twenty-four hours by Pb[1] and then transferred them to non-Pb-containing culture solutions, and after eighteen hours determined the mitotic index.

Comparing Growth and Mitotic Index of Pb-retarded Roots subsequently allowed to grow in Pb-free Culture Solutions (A) with Roots grown in Pb cultures only (B).

Pb-ion Concentration.	Growth Increment.		Mitotic Index.		
	A.	B.	A.	B.	Individual Counts.
mg.	Per cent.	Per cent.			10 mg. Pb
25.0	26.5	5.5	3.7	0.5	0.5:0.6:0.3:0.4:0.5:0.4:0.5:0.6
5.0	64.0		10.0		
5.0	81.3		9.4		
5.0	55.5		13.5		
5.0	64.3		15.2		2.5 mg. Pb
2.5	85.0	17.8	12.2	1.7	1.6:1.7:1.9:1.6:1.1:1.4:2.1:1.5

The results (A) given in the accompanying table are compared with those obtained from roots taken directly after growth in the Pb-containing culture solutions (B).

The A values, therefore, represent the recovery response from the treatment accorded the B series.

The growth increment values by themselves hardly justify a conclusion, since the time interval was unavoidably longer in the A than in the B series. On the other hand, the differences may be valid, since I have noted, but not recorded, the fact that roots left in Pb-culture solutions for more than a day hardly increase in length over that which obtains at the end of the first twenty-four hours. The marked superiority in mitotic index values, however, indicating as it does a far greater cell proliferation activity, is striking proof that growth recovery after Pb-retardation is possible.

Particular note should be made of the fact that roots subjected to a Pb-ion concentration of 5 mg. per litre showed some seven times as many mitoses per 100 nuclei after transference to Pb-free culture solutions as roots subjected to only half the concentration (2.5 mg.), but not subsequently removed from the Pb environment. In view of this, and since root growth in length is to a great degree dependent upon the rate of cell division in the meristematic region, it is probable that the greater growth increment of the A series does in part at least represent a real renewal of length growth.

The results of these experiments show conclusively that the retardative influence of Pb on growth by increase in cell number is not a permanent affair in roots. This is no proof that a like recovery of cell proliferative activity would occur in animal forms under either normal or pathological conditions with cessation of Pb administration. Yet the biological hint afforded should serve as a warning against too high expectations from the use of Pb, or indeed any other metallic element, in the treatment of malignant growths.

In concluding I might state that the details of technique used in this investigation are to be found in the papers cited. They have not been repeated here, in order to save space.

PROGRESS IN ANAESTHESIA FROM THE SURGEON'S STANDPOINT.

BY

BASIL HUGHES, D.S.O., M.A., M.B., B.CH.CAMB., B.Sc.LOND., F.R.C.S.,

SURGEON TO BRADFORD MUNICIPAL GENERAL HOSPITAL; HONORARY SURGEON TO BRADFORD CHILDREN'S HOSPITAL.

SINCE the great war, and no doubt as a result of experiences gained from it, the science of anaesthesia has been advanced in certain clinics in this country and on the Continent. Unfortunately, however, the advance at present is slow, and it may be said that, in so far as many clinics to-day adopt inhalation narcosis for practically all operations, irrespective of their magnitude or the condition of the patient, surgical anaesthesia has not kept pace with the requirements of modern surgery. Shock following a severe operation is generally attributed to the manipulations of the surgeon—perhaps a justifiable charge if rough usage of the tissues has occurred. But even the surgeon who handles the tissues with deliberate, gentle, and dexterous movements has his quota of failures in severe and prolonged operations when inhalation narcosis with ether or chloroform has been employed.

In operations demanding complete muscular relaxation inhalation narcosis may necessitate administration of large doses of the narcotic, with the production of serious toxic effects upon the myocardium, the liver, the suprarenal glands, the central nervous system, and, indeed, the tissues generally. Furthermore, the employment of this type of anaesthesia necessitates pre-operative preparation of the intestinal tract. The patient enters the theatre with an empty gut, and often three or four days pass before he is able to take solid food. Four or five days' starvation takes its toll even of a healthy individual; how much greater must be the effect upon a patient who has undergone a severe operation! Add to this the pain and exhaustion resulting from post-anaesthetic vomiting, and it may be conceded that neither the surgeon nor the anaesthetist may be responsible for failures which follow prolonged anaesthesia by inhalation narcosis, but that it is the anaesthetic which is at fault.

On February 25th, at the Medical Society of London, Professor A. H. Burgess of Manchester, opening a discussion on acute intestinal obstruction,[1] stated that, excluding cases of strangulated hernia and intussusception, the mortality resulting from operations for the relief of this condition during the period 1920 to 1924 in seven leading hospitals was 37.9 per cent. No mention was made of the anaesthetic used, but I hope I am not wrong in assuming that it was some form or other of inhalation anaesthesia, as in a series of fifty similar cases operated upon by me during the period 1926–28, using spinal and block anaesthesia, the mortality was only 13.6 per cent. In view of the very different results obtained in these two series of cases I propose as briefly as possible to describe the procedure as regards surgical anaesthesia at the Bradford Municipal General Hospital.

Rectal Ether.

For operations on the head, neck, mouth, and thorax, including trephining for cerebral tumours, trigeminal neuralgia, extirpation of goitre (especially toxic goitre), total laryngectomy, and radical excision of the breast, rectal ether, and more recently avertin (tribromethyl-alcohol), are the anaesthetics of choice. After trying several mixtures the following formula for rectal ether has been adopted for some time as giving uniformly good results.

Magnesium sulphate	2 oz.
Glucose	1½ oz.
Olive oil	1 fl. oz.
Acacia	5½ dr.
Ether	4 fl. oz.
Paraldehyde	4 fl. dr.
Morphine sulphate	1/4 grain
Water	to 12½ fl. oz. (approx.)

Rub the acacia with olive oil in a dry mortar, dissolve the magnesium sulphate and glucose in 7 oz. of water, then add 1 fl. oz. of this solution to the acacia and olive oil; gradually add the remainder. Transfer to bottle of 16 oz. capacity and add the morphine sulphate, previously dissolved in water. Dissolve the paraldehyde in ether and add gradually, shaking well. Make up to 12½ fl. oz. (approximately). Secure the cork with string and keep in a cool place.

The anaesthetic solution should be made up the evening before operation, securely corked, and kept in a cool place. It is not safe to use a solution that is thirty-six hours old.

The solution is introduced high up into the bowel by means of a rubber catheter, and the procedure is best carried out in a dark room. The introduction requires twenty minutes for its completion, and during this period there may be, though very rarely, an interval of excitement. The onset of anaesthesia varies; it may follow immediately after the anaesthetic has been completely introduced into the bowel, but more often it occurs from ten to twenty minutes later than this. A smell of paraldehyde is readily, and of ether faintly, detected in the patient's breath. It has been suggested, I think with some reason, that in making up the mixture the ether is converted into ethyl sulphate and absorbed as such. This anaesthetic is ideal for operations on the head and neck, and has the following added advantages:

1. There is no anaesthetist's apparatus to hamper the surgeon.
2. The patient's respiration is quiet and uniform, resembling that of normal sleep.
3. The patient's colour is perfect throughout.
4. There are no toxic after-effects, and vomiting does not occur.
5. Following the operation the patient has a refreshing sleep, lasting three to four hours, after which he is able to take nourishment.
6. According to our experience the anaesthetic is absolutely safe, and has no harmful effects upon the bowel.

As a routine the bowel is washed out when the patient returns to the ward.

Combined Spinal and Splanchnic Anaesthesia.

For abdominal operations in the neighbourhood of the diaphragm—for example, partial gastrectomy, gastro-enterostomy, resection of growths of the transverse colon and the flexures, operations on the gall-bladder and ducts—spinal anaesthesia with 0.1 gram stovaine introduced between the second and third lumbar vertebrae combined with splanchnic anaesthesia (60 to 70 c.cm. of a 0.5 per cent. solution of novocain), given according to Braun's method, is the anaesthetic of choice. The combination is used because, for operations lasting over an hour, spinal anaesthesia by itself is not sufficient. The anaesthesia can be prolonged if necessary by administering a further dose of the splanchnic anaesthetic and infiltrating the peritoneum and abdominal muscles with 0.5 per cent. novocain in 1 in 200,000 adrenaline solution. To nervous patients about to undergo an operation which is likely to be prolonged we have given, in addition to the spinal anaesthetic, a dose of avertin by the rectum sufficient to produce a quiet sleep, and thus unconsciousness of the surroundings and of the heat, which some patients find distressing. This anaesthetic combination has the following advantages:

1. It secures complete and uniform muscular relaxation.
2. Diaphragmatic movements are damped down to a minimum.
3. There is a marked absence of post-operative shock.
4. The anaesthetic is non-toxic.
5. Post-anaesthetic vomiting and chest complications do not occur.

Professor Finsterer, whom I have watched and assisted at his work in Vienna, would take three hours or more to perform the extensive operation of partial resection of the stomach for jejunal ulcer following previous gastro-enterostomy, using block anaesthesia to enter the peritoneal cavity, and splanchnic anaesthesia as advocated by Braun; he would repeat the splanchnic anaesthetic, but never more than once. I visited the subjects of these operations afterwards and found very little evidence of post-operative shock. Moreover, inhalation narcosis could not have secured *the certain and continued relaxation and the safety rendered possible by the above measures.*

Spinal Anaesthesia.

For operations about and below the umbilicus—for example, in acute appendicitis, acute intestinal obstruction, strangulated umbilical hernia, pelvic operations in the female, operations on the bladder, excision of the rectum, haemorrhoids, and so forth—spinal anaesthesia, achieved by introducing 0.05 to 0.1 gram of stovaine into the theca between the third and fourth lumbar vertebrae, is the method of choice. It is also ideal for all operations of magnitude on the lower extremities, and has the same advantages as the anaesthetic combination described above. In operations for intestinal obstruction spinal anaesthesia confers an added advantage: the caecum can be exposed without escape of viscera, and if distended it can be tapped. The action of stovaine being to cause strong and active peristalsis, the tapping is followed by rapid emptying of the gut. In cases of intestinal obstruction it is more than ever essential to use an anaesthetic of minimum toxicity but affording complete and uniform muscular relaxation.

Infiltration and Block Anaesthesia.

This anaesthetic (solution of novocain 0.5 per cent. in adrenaline 1 in 200,000) has been freely used alone in such instances as strangulated herniae in very old bronchitic subjects, for caecostomy in cases of acute intestinal obstruction where the toxic effects are very marked, and for amputation for gangrene in old people who have accompanying serious constitutional complications. For removal of superficial tumours—for example, lipomata, etc.—infiltration anaesthesia is the one of choice.

Avertin.

I first saw this compound used in Berlin by Professor Katzenstein in December, 1927, and was impressed by its properties; I have since used it in over a hundred cases, and find that, though not in itself a complete analgesic, it is a powerful amnesic. It is useful in combination with infiltration anaesthesia in adults and older children, and with light ether anaesthesia in younger children. Combined with infiltration anaesthesia it may be used in cases of operation for goitre, appendicitis, hernia, excision of the breast, and so forth. It is entirely non-toxic, and must find a useful place both in general surgery and obstetric practice.

For the reduction of fractures avertin in combination with local anaesthesia is ideal, and is used extensively on the Continent: 50 to 60 c.cm. of 0.05 per cent. novocain solution in 1 in 200,000 adrenaline are injected into the blood clots surrounding the fractured ends of the bone. The surgeon, having ensured that his needle has entered the blood clot by withdrawing blood-stained fluid into the syringe, may carry out the necessary manipulations in a perfectly painless manner five to ten minutes after the injection.

I would say in conclusion that since using the above-described method of anaesthesia I have witnessed a 50 per cent. fall in the mortality from my abdominal operations. I hope the time is not far distant when ether and chloroform narcosis with their inevitable mortality will have been superseded.

APPARENTLY SPONTANEOUS RUPTURE OF THE NORMAL SPLEEN.

BY

D. H. PATEY, M.S., F.R.C.S.,

SURGEON TO OUT-PATIENTS, HAMPSTEAD GENERAL HOSPITAL.

IT is a fact well known to all surgeons that in various pathological conditions, of which chronic malaria affords the best example, the spleen may rupture following the slightest degree of trauma, or even without injury at all. To the latter condition the term "spontaneous rupture" is applied. Rare cases have been reported in which it is claimed that a similar spontaneous rupture has taken place in a perfectly normal spleen. That a healthy spleen should without apparent cause suddenly burst is difficult of belief, and the following case is recorded as offering an explanation of the anomaly.

The patient was a fairly well-covered and muscular male, aged 50, by occupation a shopkeeper. He stated that he had previously been quite healthy, and that he was one of a large family all of whom were healthy. He gave a history that on the evening of March 12th, 1927, he suddenly, and without apparent cause, experienced acute pain in the epigastrium, which within a few minutes became so severe that he had to stop work. The pain later spread to both his shoulders. He went to bed, but was not seen by his doctor until March 14th, when he was immediately ordered to hospital.

On admission the patient looked extremely ill, his face being pale and covered by a cold sweat. The temperature was 99° F., and the pulse 120; the respirations were shallow and grunting. The tongue was slightly furred. The abdomen did not move on respiration, and was uniformly rigid to superficial palpation. Deep tenderness was present all over the abdomen, being most marked in the epigastrium. A rectal examination was negative. The patient was regarded as a typical case of perforated gastric ulcer, which diagnosis was made independently by his doctor, the house-surgeon, and the surgeon.

Operation (March 14th).—The abdomen was opened by a right paramedian upper abdominal incision. Immediately on opening the peritoneum there was a profuse outpouring of blood, at first dark and old, but later mixed with fresh blood. Investigation showed the spleen to be the source of the haemorrhage, and the organ was removed after the left rectus muscle had been divided transversely to obtain better access. The patient was by this time very collapsed; an intravenous saline was therefore given on the table, while the abdomen was rapidly closed with through-and-through sutures. The patient rallied well from the operation, and had a normal uneventful convalescence. He was discharged on April 11th.

Macroscopical Appearance of the Spleen.—The normal appearances of the spleen were almost completely obscured by two large subcapsular haematomata, one situated on the outer convex surface, the other on the concave side of the organ, the two communicating with each other round the posterior border. The only normal spleen visible was a narrow strip along the anterior border. The haematoma on the convex aspect of the organ had ruptured through the capsule at one point, and it was through this rupture that the haemorrhage into the abdomen had taken

place. The vessels in the hilum of the organ appeared healthy. On section the diagnosis of subcapsular haematoma was confirmed, and it was in addition seen that a considerable portion of the splenic substance had been ploughed up by the haemorrhage.

Microscopical Examination.—A portion of the spleen which appeared to be undamaged by the haemorrhage was submitted to microscopical examination. A normal histological picture was found. A portion of the splenic artery was also examined, but no abnormality was discovered.

As far as could be judged, therefore, apart from the damage caused by the haemorrhage, the spleen was a normal healthy organ of the usual size and with healthy blood vessels. The patient was repeatedly questioned as to whether he had received any injury, but this was denied. A diagnosis was therefore made of spontaneous rupture of a normal spleen.

Shortly after his discharge the patient was asked to attend in order that he might be further examined, and investigations were made to see if some cause could be discovered to account for the apparently spontaneous rupture. No abnormal signs were found in the heart, lungs, or abdomen. The urine was acid, and contained no abnormal constituents. The arteries were slightly thickened and the blood pressure was 140/85. While the examination was in progress the patient stated that he had lately remembered that at 10.30 a.m. on the day of the onset of his illness he was leaning over a ledge in order to open his shop window, when he slipped and fell on to his left side against the edge of the ledge. He had only slight discomfort, and, thinking nothing of his injury, dismissed it from his mind until our repeated questionings recalled the incident. Undoubtedly this forgotten trauma was the primary cause of the ruptured spleen.

Similar cases have been reported by T. S. Jackson[1] and J. L. Stretton.[2] Jackson's patient was a girl, aged 15, in whom the apparent spontaneous rupture occurred while she was sitting in a cinema. After her recovery he elicited the history that four weeks previously she had fallen against a desk, striking her left side. Stretton's patient was a pregnant woman, aged 37, in whom the lesion professedly followed the getting out of bed to pass urine. Subsequent careful inquiry elicited a story of violent coitus.

M. P. Susman[3] reports, as a spontaneous rupture of an apparently normal spleen, a case the clinical features of which bear a close resemblance to the one recorded here, and in which the original diagnosis was also perforated gastric ulcer. He could find only six similar cases in the literature.

Admitting that spontaneous rupture of a perfectly healthy spleen can hardly occur, he suggests as an explanation that some lesion was present which was responsible for the rupture, though evidence of its existence was destroyed by that occurrence. In other words, we are dealing with examples of spontaneous rupture of pathological spleens. It seems simpler to believe that occasionally, in certain individuals and at certain phases, rupture of a normal spleen may occur following minimal trauma. If the capsule is intact the symptoms may be delayed for hours or days, and when eventually the patient collapses the memory of the original and causative injury has disappeared. The case here recorded affords a good example of this happening.

A NOTE ON HAEMATOCOLPOS.

WITH A REPORT OF TWO CASES.

BY

ALBERT SHARMAN, B.Sc., M.B., CH.B.GLASG.,

LATE RESIDENT SURGEON, ROYAL ALEXANDRA INFIRMARY, PAISLEY; EXTRA DISPENSARY SURGEON, ROYAL SAMARITAN HOSPITAL FOR WOMEN, GLASGOW.

HAEMATOCOLPOS is a very uncommon affection, and is the result, generally, of cryptomenorrhoea, the condition in which the formation of the menstrual discharge goes on, but without the normal appearance of menstruation. Two cases which recently came under my notice and presented features of much interest prompt a review of the general points and symptomatology of the condition.

The patient is generally between 15 and 18 years of age,[1] and is usually brought to medical notice on account of one or other of three things: (1) non-appearance of menstrual periods; (2) swelling in the abdomen; (3) disturbance of micturition.[2]

In most cases subjective symptoms of the menstrual period are present, and these tend to be better defined in older girls. The obstruction to the escape of the menstrual discharge may be anywhere below the internal os, and its commonest site is the ostium vaginae, where a diaphragm is present, formed by the non-canalization of the lower end of the fused Müllerian ducts, and not by an imperforate hymen.[3] In some cases the normal hymen may be seen external to the obstructing membrane, but in others there is no trace of the hymen whatsoever, and some observers have described this type as due to a true imperforate hymen.

De Sahn[4] many years ago, in a review of the condition, stated that the error of formation is never very great, as it would then promote atrophy of the internal genitals, especially of the ovaries, and menstruation would not occur. He pointed out factors leading to stenosis of the vaginal canal, such as inflammatory or specific ulceration of the vagina, chronic vaginitis, cicatricial constriction following injuries during labour, or an attack of small-pox or typhoid fever, and, possibly, cancer obstructing the vagina. These latter cases must be very rare and may be considered separately from those under consideration now, which can be conveniently termed primary or membranous haematocolpos.

CASE I.

The patient, a girl aged 13 years and 8½ months, was admitted to Paisley Royal Alexandra Infirmary on January 17th, 1929, under the care of Mr. Hugh Donald.

History.—Four months before admission to hospital the girl complained of slight pain in the abdomen. This persisted for an afternoon, during which her mother detained her from school. Between three and four weeks later slight pain recurred, and lasted for about three hours; it was not severe enough to keep her from attending school. Another mild attack appeared between three and four weeks later, and, like the others, was referred to the "middle of the stomach and low down." A similar interval elapsed until the next attack, which was more severe than the others, but only lasted about four hours. The next spasm occurred three weeks later, and was sufficiently severe to make her seek medical advice, and to be detained in hospital. Five days before admission she had a sharp and moderately severe epistaxis, with no accompanying symptoms. The following morning she was given Epsom salts at home, and in the evening complained of slight pain in the abdomen, similar to that which she had previously been experiencing, but which her mother attributed to the purgation. The next afternoon she was crying with the pain, which persisted all the evening. On the following day the pain was still more severe; it was situated just below the umbilicus, and for the first time necessitated her remaining in bed. Her mother stated that the pain seemed to be cramp-like, as, at short intervals, the girl would cry out as a painful spasm occurred. This persisted until the next day, when pain on micturition became an added feature. The painful micturition and spasmodic attacks of evidently severe pain, causing her to roll about in agony in bed, made her family doctor suspect urinary calculus, and he sent her to hospital.

On examination the patient was found to be a well-nourished and well-developed girl, the secondary sex characters being well formed. Deep tenderness was elicited in the middle line of the abdomen between the symphysis pubis and one inch below the umbilicus, and this tenderness was also present, extending for about two inches from the mid-line on the left side, but not on the right. A distinct mass could be felt in this situation through the abdominal wall, but its outline could not be defined. Rectal examination proved excessively tender, but a large, soft swelling was readily made out, bulging into the anterior rectal wall, and haematocolpos was diagnosed. When the condition is kept in mind, diagnosis is simple. While in the ward before operation she had one severe spasm of pain, which was relieved by 5 grains of aspirin. There was no albuminuria.

Treatment.—Under anaesthesia, examination of the hymen revealed it to be bulging, deep red in colour, and quite imperforate. A very freely movable tumour was palpated through the abdominal wall with its upper border about one inch from the umbilicus. The abdomen was opened in the mid-line and the tumour found to be the uterus distended with blood; the ovaries and tubes were examined and found normal. Laparotomy was justified to observe the condition of the Fallopian tubes, as haematosalpinx would most probably have necessitated their removal. The hymen was vertically incised under scrupulous asepsis, and one pint of dark red, jelly-like fluid escaped. The external os of the cervix admitted one finger readily. The condition was, then, haematometra. The vulva was swabbed with spirit and iodine, but no vaginal cleansing was employed. The vulva was swabbed with spirit daily, and the patient made an uninterrupted recovery, being dismissed on February 26th. Menstruation, to that date, had not yet reappeared.

CASE II.

This patient, aged 14 years and 2 months, was admitted to the Royal Samaritan Hospital for Women on February 17th, 1929, under the care of Dr. John Gardner.

History.—Seven days before admission she complained of a low backache, which she ascribed to sitting on a high stool at piano practice. This continued slightly and intermittently until the evening before admission. She retired to bed at the usual hour, but was awakened at 2 a.m. with severe colicky pain in the lower abdomen. This continued almost continually throughout the night, but there was no sickness or vomiting. About 7 a.m. she complained of a strong desire to urinate, but passed only a small quantity of urine (amount unspecified). From that hour until admission to hospital at 6 p.m. on the same day there was marked vesical tenesmus and complete inability to micturate.

On examination the patient was found to be well nourished. She was obviously in great discomfort and the lower abdomen was markedly distended, the percussion note being dull to within an inch of the umbilicus. Twenty ounces of urine were withdrawn by catheter, and the patient immediately and spontaneously declared her great relief and comfort. There was no albumin or any abnormality in the urine. The temperature was 97.6° F. and the pulse rate 92. The ostium vaginae was occluded by a reddish bulging membrane, which showed a marked impulse on coughing. Rectal examination revealed a fairly firm mass, palpable through the anterior rectal wall. No tumour could be felt through the anterior abdominal wall, and there was only slight suprapubic tenderness. The case was diagnosed as simple haematocolpos.

Treatment.—The hymen was incised vertically, and each edge sutured to the adjacent skin. About five ounces of thick menstrual fluid escaped. No douching was employed, but daily swabbing of the vulva with mild antiseptics, and recovery was uneventful.

Comment.

The features of special interest in Case i are: (1) the unusually early age of the patient to have haematocolpos and haematometra—13 years 8½ months; (2) the predominant symptom that caused the girl to be sent to hospital—severe abdominal pain, probably caused by spasmodic contractions of the uterus; (3) marked epistaxis on the day before the onset of pain.

The feature of note in Case ii is undoubtedly the very acute retention of urine; and, of course, the absence of any previous monthly disturbance or premonitory symptom, except the slight backache of one week's duration.

I am much indebted to Mr. Hugh Donald for permission to publish Case i, and to Dr. Gardner for Case ii.

A CASE OF ALEUKAEMIC LYMPHATIC LEUKAEMIA.

BY

J. H. GROVE WHITE, B.A., M.D.DUB.,
PHYSICIAN TO THE CIRENCESTER MEMORIAL HOSPITAL;
AND
J. B. DAVEY, M.B.LOND.,
HONORARY PATHOLOGIST, CHELTENHAM GENERAL HOSPITAL.

The case here recorded revives the controversy as to the existence of really acute lymphatic leukaemia to which one of us, in conjunction with L. E. H. Whitby, refers in a paper, "Some difficulties in the diagnosis of leukaemia," published in the *Lancet* of June 18th, 1927 (p. 1279). The present patient was in good health until October 1st, 1928; the duration of her illness was six and a half weeks; cases of acute myeloblastic leukaemia, it is true, may terminate even more rapidly. The degree of haemorrhage no doubt largely controls the period of survival.

A single woman, aged 25, employed as a monotype operator, was first seen professionally in 1925. She was then found to be chlorotic. She took but little outdoor exercise, and was advised to play games and go walks. The adoption of this advice led to rapid improvement, and she enjoyed good health until the beginning of October, 1928. The conditions under which she worked were quite satisfactory, but she had always had a "delicate throat," was very sensitive to the smell of smoke, and could not tolerate gas fires. Her previous medical history revealed nothing else of importance.

Present Illness.

On October 1st, 1928, she developed a "feverish chill" and was sent to bed; a week later the symptoms were chiefly gastric, and by October 15th she was up and about again. On October 22nd she was referred to a throat specialist on account of a complaint of foul-tasting discharge from the nose, but nothing was found in the nose, nasopharynx, or sinuses to account for her symptoms. On October 27th she developed what appeared to be a typical attack of rheumatism, the pains flying from joint to joint and yielding to sodium salicylate. On November 2nd she was seen on account of bleeding from the gums and the passage of tarry stools; no evidence of valvular disease of the heart was found. The haemorrhage continued, uninfluenced by calcium—by the mouth and intramuscularly—or haemoplastin.

On November 9th enlargement of the spleen was detected, and some discomfort was complained of in that region. Petechiae on the buttocks now appeared, and diarrhoea with dark stools and haematemesis occurred. Her condition rapidly deteriorated. She was admitted to the Cirencester Memorial Hospital on November 12th; from that time until her death, two days later, her temperature ranged between 100.6° and 103° F.

On November 13th a blood examination was made. The blood was extremely thin, and with the Dare haemoglobinometer the haemoglobin value was found to be about 9 per cent.; the red cells 1,050,000 per c.mm.; colour index 0.5; leucocytes 1,100 per c.mm. A differential count of 250 leucocytes gave:

	Per cent.
Polymorphonuclears	0.4
Neutrophile promyelocytes	2.4
Neutrophile metamyelocytes	2.4
Eosinophile myelocytes	0.4
Myeloblasts	1.6
Lymphocytes (mostly small forms)	84.4
Turck's cells	1.6
Lymphoblasts	6.0
Large mononuclears	0.0
Eosinophils	0.0
Unclassified	0.8
	100.0

No nucleated red cells were found. There was a moderate degree of anisocytosis and slight poikilocytosis. A few basophilic red cells were present. A film stained by Graham's oxidase method gave: oxidase granule containing leucocytes 8 per cent., non-granulars 92 per cent.,—a finding which agrees closely with the differential count from a Leishman-stained film described above.

Post-mortem Examination.

At the necropsy on November 15th, twenty-one hours after death; small subcutaneous haemorrhages were noted on the left upper eyelid, on the buttocks, and one on the right thigh; rigor mortis was present. The body was not emaciated. Subcutaneous fat was fairly abundant and of normal colour. No enlarged superficial glands were detected. There was no excess of free fluid in the abdomen.

The spleen was enlarged, about 8 in. long, and of normal consistence. Malpighian bodies were visible; on section nothing noteworthy was found. There was much perisplenitis, but only slight thickening of the capsule. The liver was of normal size; on section it was greasy-looking and pale. The pancreas was normal, as also were the kidneys.

In the great omentum and in the portal fissure were a number of enlarged glands, mostly about the size of filberts; they were pale pinkish on section, and some showed haemorrhages. There were several small subperitoneal haemorrhages in the course of the intestinal tract, and two large ones, one extending over about two inches in the mid small intestine and another about the caecum.

There was slight excess of free fluid in the pericardial sac, yellow in colour; several petechial haemorrhages on the visceral pericardium. There were no valvular changes. The lungs were pale, with no adhesions; two or three subpleural petechiae were present. The marrow in the ribs appeared red.

Portions of the liver, spleen, a gland from the mesentery, and of a rib were fixed in Holly-Maximow fluid and sections stained by Ellermann's method, as described by Piney in *Recent Advances in Haematology*; other portions from the same sources were fixed in formol saline and stained by haematoxylin and eosin. The report on these was as follows.

Liver.—The portal canals are everywhere infiltrated with lymphocytes which, in places, penetrate a little way into the outer parts of the lobules, some liver cells being cut off, as it were, by them. A similar invasion is seen in the deeper part of the capsule of Glisson. Some of the liver cells round the hepatic veinules show vacuolation (fat globules, dissolved in dehydration).

Gland.—There is but little indication of lymph nodes and germ centres, lymphocytes being fairly evenly distributed throughout cortex and medulla, though they are somewhat denser under the capsule. Besides lymphocytes there are many larger rounded or oval cells with large round nuclei; some of these cells contain two or three nuclei. Some of the trabeculae are thickened, and the larger cells are, in places, disposed along the trabeculae.

Spleen.—Malpighian corpuscles small and inconspicuous; phagocytic cells scanty. No fibrosis. Lymphocytes everywhere abundant.

Rib.—The marrow consists mainly of lymphocytes, some larger cells (? myeloblasts) seen. Red blood cells not numerous.

We think that there can be no question of the correctness of the diagnosis of lymphatic leukaemia, though we can find no record of a case with such extreme leucopenia. The sections of the liver were typical of lymphatic leukaemia, those of lymphatic gland and spleen very suggestive of that condition. The sections of the rib were less successful and convincing.

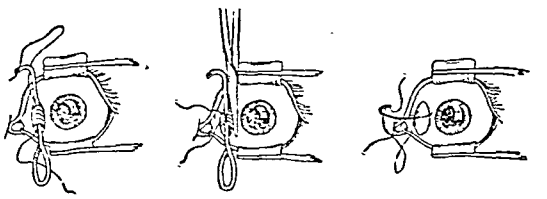
We have to thank Dr. L. E. H. Whitby, *M.C.*, for examining the sections and giving his opinion on them.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

CONCOMITANT CONVERGENT STRABISMUS: EPITOME OF TREATMENT.

SQUINT is a preventable defect. At about 3 years of age judicious use of a collapsible tube of atropine ointment permits predisposing refractive errors to be discovered and provides an effective mode of preventive treatment. The left eye tends to deviate more often than the right.



Unfortunately all children are not examined before they go to school. The amblyopia of an established squint concerns the brain rather than the eye, hence glasses are slow to cure it: an occluder of Chavasse's 6/60 glass is usually prescribed for the straighter eye until fusion training becomes worth while.

As a last resort a modified recession operation has yielded good results in 200 consecutive cases. With the aid of a miniature-eyed strabismus hook, made to my design in stainless steel (Weiss), the internal recti are ligated, detached from their insertions, and sutured to the tough outer layers of the sclera further back, as shown in the accompanying diagrams. The suture material is 000 twenty-day chromic catgut (Davis and Geck). Both eyes are covered for forty-eight hours, and the formerly fixing eye is kept covered for three weeks.

The organization of the Bradford School Medical Service ensures effective following up of the cases.

W. O. LODGE, M.D., F.R.C.S.Ed., D.O.M.S.
(From the Bradford Pre-School Clinic)

ALOPECIA AREATA ASSOCIATED WITH FRONTAL SINUS DISEASE.

THE following case is of interest in view of the recent work of Wright,[1] who has shown that the theory of reflex irritation as a cause of alopecia areata is untenable and that it is unlikely that this disease is a trophoneurosis.

A healthy-looking man, aged 30, consulted me in January of this year on account of a patch of baldness the size of a penny situated in the left temporal region. He stated that the hair had begun to fall in October, 1928, but that the baldness was limited to this spot and that no other area had been involved.

On examination the condition was found to be alopecia areata and the patch corresponded, according to Jacquet,[2] with the site of maximum predilection for the disease. The patient stated that he had had much domestic trouble during the past year owing to the illness of his wife. In February, 1928, he had had severe pain in the right frontal region, which lasted for several days and then completely disappeared; further attacks had occurred in September, 1928, and January, 1929. On my advice the patient saw Mr. E. Watson-Williams, who reported that a skiagraphic examination confirmed the diagnosis of right-sided frontal sinus disease. As the patient was unwilling to undergo an operation, the scalp was treated by local measures. At the beginning of April he had on one occasion a free discharge of pus from the right nostril. He has had no further symptoms of sinusitis since January, and when seen at the end of April hair was beginning to grow on the bald patch. No new areas of alopecia have developed.

It would be difficult to explain the relationship in this case between a right-sided frontal sinusitis and a left temporal patch of alopecia on the basis of reflex irritation, and we are therefore led to the conclusion that the focal infection *per se* was responsible for the disease.

AN EXTRAORDINARY TUMOUR.

HAVING read the note on "an unusual tumour" by Dr. R. L. Paterson in the *British Medical Journal* of January 5th (p. 16), I have been reminded of a case of mine which was very much like the one there described.

A Pathan woman, aged about 50, came to me in August last with a large, pendulous, pear-shaped growth on the left side of her body. It started a little above the costal margin in a comparatively narrow skin pedicle, increasing in size from above downwards and reaching down to the middle of the thigh. The growth was lobulated and of soft consistency; there were multiple old scars over its dependent part, and some varicose veins over its surface. The growth had commenced twenty years previously, and apart from its objectionable bulk caused no great inconvenience.

The tumour was diagnosed as a lipoma, and was removed. The patient left the hospital on the ninth day after operation, well gratified with the result.

The accompanying photograph, taken just before the operation, illustrates the extent of the growth, and may be of interest.

SAEED AHMAD, M.B., B.S.,
Assistant Surgeon, Provincial Hospital, Peshawar, India.

A CASE OF THREE-LOOP INGUINAL HERNIA.

CONSTITUTING as it does a trap for the uninitiated, I thought it well to publish the following case in order to impress juniors with the necessity, when operating on a hernia with a double loop of bowel in the scrotum, to bring down and examine the intervening abdominal loop, no matter how healthy the portions in the scrotum appear to be. I would also commend to juniors the method of dealing with a very doubtful loop by enveloping it in oiled gauze. It may not constitute brilliant surgery, but it enables a very rapid and efficient operation to be performed, even when the patient is critically ill, and has been used with success in cases where the patient was very old and very ill, and yet, although the loop went gangrenous, the patient recovered.

A labourer, aged 24, was admitted to the Eastern District Hospital, Glasgow, in December, suffering from a huge strangulated inguinal hernia of the right side. He stated that he had had this hernia as long as he could remember, and, although it grew gradually larger, he was always able to reduce it until the day of admission, when it suddenly became very much larger, painful, and irreducible.

At operation three loops of small intestine, probably ileum, were found, involving fully three feet of bowel in all. Two of these loops were only separated from one another by about six inches of bowel, but they again were separated from the third loop by an intra-abdominal portion about eighteen inches long. While the portions in the scrotum looked healthy, that which was withdrawn from the abdomen was black, and so much affected that its vitality appeared doubtful. The doubtful portion was therefore enveloped in oiled gauze, and the patient returned to bed. Two days later it was inspected, found to be recovering, and was returned to the abdomen, and the wound closed, but radical cure was not performed, as the patient's condition was still unsatisfactory. About six weeks later the scar was excised and the radical cure performed, the patient making an uneventful recovery.

So far as I am aware, Lauenstein of Hamburg was the first to draw attention to these double-loop, or W, herniae,

as he called them, and the tendency in these herniae for the intra-abdominal loop, connecting the two scrotal loops, to become gangrenous, while the scrotal loops escape. I had published a couple of cases of double-loop hernia on which I had operated, and Lauenstein sent me a copy of an article he had written reporting a number of such cases, in most of which the abdominal loop had become gangrenous.

J. MACEWEN, M.B., C.M., F.R.F.P.S.,
Surgeon, Glasgow District Hospitals.

CHRONIC TEMPORO-SPHENOIDAL ABSCESS.

IN view of the difficulty of diagnosis in the earlier stages, and the ultimate recovery of the patient, the following case appears to be worth recording.

A boy, aged 5, was admitted to the Royal South Hants Hospital, Southampton, on December 10th, 1928, complaining of feeling sick and having a headache. The mother stated that for fourteen days previously he had had a foul discharge from the left ear, accompanied by attacks of giddiness and unsteadiness of gait. There was no history of infectious disease or of any other previous illness.

On admission the temperature was 100° F., the pulse 120, and the respirations 26; there was a profuse foul-smelling discharge from the left ear, but no swelling or tenderness behind, and no tenderness on firm percussion above it. During the next week the patient became listless, and, later, very drowsy, sleeping most of the day. He vomited on two occasions and the ear continued to discharge profusely. The temperature ranged between 98.8° and 102.4° F. From December 22nd to 27th the condition gradually improved, and the child appeared much brighter. Pain was felt over the left mastoid area on December 28th, and there was slight tenderness, but no swelling or oedema was present. No pathological change was found in the fundus of either eye.

On January 7th, 1929, vomiting recommenced for the first time since the middle of December; the child became very drowsy, and the left pupil was slightly larger than the right. The temperature was now 105° F., the pulse 124, and the respiratory rate 24. The left mastoid antrum was explored, and also the left lateral sinus and middle fossa of the skull on the left side after trephining, but nothing abnormal was discovered. For some days the patient continued to be very drowsy and disinclined for food. *Twitching of the right side* of the face was noticed on January 16th, with apparent inability to speak. There was occasional vomiting, and two days later slight twitching of the right hand appeared. The left pupil was now much larger than the right.

On the afternoon of January 21st violent twitching of the right hand and arm, and also of the right side of the face, began. The child was taken to the operating theatre and the trephine disc was removed. The subdural space was aspirated and pus was found on the left side. The dura mater was opened by a crucial incision overlying the left temporo-sphenoidal region, and the abscess was left to drain. The child began to speak soon after regaining consciousness, and the condition subsequently improved each day. He was discharged from hospital on February 26th, a small hernia cerebri being present at the site of the trephine opening.

I am indebted to Mr. H. G. G. Nelson for permission to publish the case.

R. VAUGHAN THOMAS, M.B.,
Late Senior House-Surgeon, Royal South Hants Hospital, Southampton.

Reports of Societies.

FISTULA IN ANO.

AT a meeting of the Subsection of Proctology of the Royal Society of Medicine, held on May 8th, the president, Sir CHARLES GORDON-WATSON, in the chair, Mr. J. P. LOCKHART-MUMMERY opened a discussion on fistula in ano.

Following a historical survey, in the course of which he mentioned that the operation for fistula was cited in a manuscript of 2200 B.C., and that "cutting of a fistula" was performed by John Arderne in the fourteenth century, Mr. Lockhart-Mummery said that all fistulae were due to peri-ano-rectal inflammation and suppuration, but were less common now than they were ten to fifteen years ago. Summarizing the various causes of the disease, he said that in the substance of the internal sphincter there were present glandular spaces called intramuscular glands. These glands communicated with the submucous tissue in the region of the lower end of the rectum and anal canal. Inflammation of these glandular elements was probably the starting-point of many cases of infection in this region. Congenital fistulae were due to inclusion dermoids lined with skin and containing hair and sweat glands. Their situation was typically over the coccyx and lying well behind the anus. Very chronic fistulae were often lined with skin, which had grown in from the external opening, but contained no hairs or sweat glands. Tuberculous fistulae differed clinically and histologically from other types by the lack of induration surrounding the track. Tuberculous granulation tissue infiltrated the surrounding tissue, and there was no limiting membrane or surrounding fibrosis. Referring to the treatment of fistula, the speaker said that there were many ways of operating, but that certain very definite principles were necessary in all cases to ensure success. Careful following of all the tracks and excision as far as possible, adequate drainage, and careful dressing of the flat wound left after operation were among the most important. He was convinced that division of the external sphincter should not be carried out at the first operation, but that a two-stage operation should be performed, particularly if the sphincter must be divided laterally. Delaying the division of the sphincter for two to three weeks after laying open the superficial tracks ensured the fixation of the divided ends of the sphincter by the surrounding fibrosis, which developed during the healing process, and prevented wide retraction. Division of the internal sphincter did not cause incontinence; the external sphincter was the chief factor in the control of the anal orifice. In dealing with very extensive and complicated fistulae treatment in stages and control of the healing process, by enabling the final opening in the bowel to be made through the posterior part of the sphincter, obviated the possibility of producing incontinence. In treating tuberculous fistula the tuberculosis as a whole should be treated as well as the fistula. Excision of the fistula should be aimed at with all the surrounding granulation tissue. Primary suture of the wound after complete excision of a fistula had not been very successful, as the wound was in such intimate relation with the anal canal. In the speaker's opinion, complete excision of the fistula, leaving a flat, open, granulating wound, was the best method of treatment. Excellent photographs and sections of various types of fistulae and sections, prepared by Dr. Cuthbert Dukes, showing the intramuscular glands, were shown.

Dr. H. A. HARRIS gave a lucid demonstration of the embryology of the rectum and anal canal. He pointed out that the primitive gut, and, finally, the fully formed alimentary tract, were poorly covered with muscles, compared with the tubes which were developed from them—for example, the trachea, bile ducts, and urogenital sinus. The poor musculature made the parent tube liable to the formation of diverticula, and, by overgrowth of the lining membrane, to occlusion. Referring to the intramuscular glands, Dr. Harris said that glandular tissue was found in the submucosa and in the muscle in various parts of the alimentary tube, such as the glands present in the oesophagus, Brunner's glands in the duodenum, and the intramuscular glands in the ano-rectal region. These glands extended outwards through and between the muscle fibres and, in the perianal region, into the loose connective tissue between the internal and external sphincters.

Mr. C. NAUNTON MORGAN gave an account of his analysis of 100 consecutive cases of peri-ano-rectal infection and fistula formation admitted to St. Mark's Hospital. The condition was very much more common after the age of 30, was three times more frequent in men than in women, and between the ages of 10 and 15 than between 15 and 20. Certain occupations were more liable to be affected than others, especially tailors, bus drivers, and clerks, and the disease was nearly twice as common in cavalry regiments as in the infantry. Most fistulae were of the direct type, and passed radially into the bowel (46 per cent.); the horseshoe variety was present only in 15 per cent. Over 50 per cent. passed superficial to the external sphincter, 33.3 per cent. deep to the sphincter, and the remainder through the fibres of the sphincter. Over half the direct fistulae were situated in front of a line drawn *transversely through the anus*. The incidence of tuberculous fistulae was 9 per cent., and pulmonary *tuberculosis was present* in about 8 to 11 per cent. of the cases. Tuberculous fistulae healed well if the patient's general condition was good and there was no accompanying pulmonary disease. In eight cases with active pulmonary tubercle only two fistulae healed, whereas four cases in five of tuberculous fistulae uncomplicated by pulmonary disease healed rapidly and

well. Exacerbation of the pulmonary condition following the operation occurred in three cases, though regional anaesthesia had been used. It was suggested that the recumbent position should be avoided after operation and the cases transferred as soon as possible to a sanatorium. Most of the cases complicated by pulmonary tuberculosis occurred in patients after the age of 40. In over 60 per cent. of the cases under consideration no exciting cause for the infection was found. Fissure and haemorrhoids accounted for only about 15 per cent., foreign bodies only 4 per cent., and inflammation of a crypt 1 per cent. Inflammation of a crypt and tearing of an anal valve might possibly be common exciting causes, but owing to the difficulty of demonstrating such minute lesions they had not been looked for up to the present in every case of fistula.

Sir CHARLES GORDON-WATSON said he thought the two-stage operation was a sound procedure. He had practised excision of fistulae and primary suture with considerable success. He described a case in which a foreign body, a bone, had produced two ischio-rectal abscesses, and also a case of very extensive rectal fistula due to a gunshot wound, with openings extending down the left thigh as far as the popliteal space. Colostomy had to be performed on this case. He thought that the intramuscular glands described by Mr. Lockhart-Mummery were possibly the cause of many abscesses in this region. The figures quoted by Mr. Naunton Morgan showed the importance of early and thorough treatment of ischio-rectal abscesses, and the results of treatment in the various groups of cases suffering from tuberculous disease were very interesting and important.

Dr. GANT (New York) said that it was easy to diagnose the average case of tuberculous fistula, and he agreed that the general condition should be treated as well as the fistula. He thought that the two-stage operation was unnecessary and that retraction of the sphincter and laxity of the anal orifice would not occur if the wound was not tightly packed. The careful after-treatment of the healing wound was as important as the operation for fistula. Dr. Gant said that he used local anaesthesia almost exclusively for fistula operation.

Mr. L. E. C. NORBURY said that in his experience tuberculous fistula healed quite well if the pulmonary condition was carefully treated. He showed a foreign body, a German bullet, which he had removed from the ischio-rectal fossa of a man who had had numerous operations for fistula without success.

Mr. E. T. C. MILLIGAN said that resolution of an infective process in this region occurred only extremely rarely, and therefore early and adequate drainage was called for to prevent extensive fistula formation. Multilocular abscesses often occurred in the ischio-rectal fossa, and they should be laid open into one cavity for drainage. Gangrene was fortunately an uncommon termination of inflammation, but he had seen one fatal case. The early signs of inflammation, heat, redness, swelling, were usually absent in the early stages and should not be waited for; deep tenderness was often the only physical sign. He thought tuberculous fistulae should be treated by wide excision and primary suture.

Mr. ASLETT BALDWIN said that he had employed ionization with some success in healing fistulous tracks.

TREATMENT OF LONG-STANDING VOLKMANN'S CONTRACTURE.

A MEETING of the Section of Surgery of the Royal Academy of Medicine in Ireland was held on April 26th, with Mr. R. A. STONEY in the chair. Mr. H. MEADE showed a case of Volkmann's ischaemic contracture treated by transplantation of the internal condyle.

Mr. Meade gave the following clinical details of the case.

A boy, aged 5, fell off a stool in 1917 and fractured his humerus. He was admitted to hospital the following day. Two days later he developed measles and was transferred to the fever ward, where he remained six weeks, during which time his arm was in a splint. His parents noticed that when he was discharged from the fever ward his fingers were bent and that he was not able to straighten them; the elbow also was in bad position. A couple of years later he underwent an operation, which gave him good use of the elbow. Nothing, however, was done to the contracted fingers, which were steadily getting worse. Shortly after he developed tuberculous disease of the knee-joint, for which he received conservative treatintermittently.

Mr. Meade first saw the patient on June 3rd, 1928, when he was consulted about the joint, which was in the third stage, with the knee ankylosed at right angles. There was a good deal of backward displacement. The patient's right hand was in a position typical of an advanced case of Volkmann's contracture; his parents considered that it was useless trying to do anything for it, but Mr. Meade obtained their leave to operate on the knee and to do what he thought best for the hand. On June 6th Mr. Meade operated on the knee, performing an erasion; he stretched the fingers and put them in splints, but did not make any attempt to dorsiflex the wrist. In three weeks' time there was a considerable improvement in the movements of the fingers, and the forearm and the hand were placed in a malleable splint. The wrist was gradually dorsiflexed and the splint was removed daily for massage. There was a steady improvement up to a certain point, when the condition became stationary. On July 19th further stretching was done under gas, without using much force; the result was a further shade of improvement. This stretching was repeated on October 25th, using more force, but producing very little improvement. Massage was still continued.

On March 13th, 1929, Mr. Meade performed the operation first described by Max Page, with the slight modification introduced by Hamilton Bailey; very little difficulty was encountered. The immediate result was disappointing, as the originator had stated, but within four weeks there was a considerable improvement, and the hand was now fully dorsiflexed with the fingers straight.

Mr. Meade said that the splint had only been removed from the fingers one week before the date of reporting, so it was impossible to say what degree of flexion would return to them. The result thus obtained in one month was, however, better than in nine months of conservative treatment, and that in a case that had been neglected for eleven years.

Mr. ARTHUR CHANCE said this method of treating contractures due to shortening of the muscles seemed to be the right one, as it was on the same lines as Souttar's operation for hip flexion. He was sure that it was much better than any lengthening of the tendons or any attempt to shorten the bones, not only because it gave a better result, but because it was much more simple to do.

Sir WILLIAM WHEELER showed an illustration of the type of Volkmann's contracture which was not uncommon in the Ministry of Pensions hospital after the war. He and his colleagues had obtained the best results from conservative treatment along the lines recommended by Sir Robert Jones. The treatment required great patience; the good results obtained were in a measure due to the fact that the patients could be kept under constant observation, and there was no lack of trained assistance from a well-equipped electro-therapeutic department. Treatment after shortening the bones of the forearm was very difficult, but some good results followed lengthening of the tendons. The pathological shortening of the tendons was only one factor in a generalized process. Stripping the flexor origins downwards from the humerus and the bones of the forearm, and transplantation of the bony origin of the muscles, were rational procedures when followed, as in Mr. Meade's case, by conservative treatment to stretch the other structures.

Mr. MEADE, replying, added that it was important to remember that a Volkmann's contraction could occur without splints being supplied.

Antitoxin Treatment of Tetanus.

Mr. R. A. STONEY showed a recent case of recovery after tetanus.

A child, aged 8 years, complained of abdominal pain on March 22nd, and was admitted to hospital as a case of tetanus. Examination showed trismus, well-marked risus sardonicus, and tonic contraction of all muscles, with recurrent clonic spasms. There was a history of injury to the great toe four days previously, and the nail was black, with pus under it. An intramuscular injection of 8,000 units of antitoxin was given at once. On the following day the nail was removed under chloroform, and dressed with hydrogen peroxide; 7,000 units of antitoxin were injected intrathecally, and 5,000 units intramuscularly. Five doses, each containing chloral hydrate 15 grains and potassium bromide 30 grains, were given at intervals of four hours; altogether 33,000 units of antitoxin were administered intramuscularly, 7,000 units intrathecally, and 6,000 units intravenously, with 240 grains of chloral hydrate. The child left the hospital well on April 17th.

Sir WILLIAM WHEELER said that he had been a member of the committee on tetanus presided over by Sir David Bruce during the war, which, after much investigation, recommended as a working hypothesis a definite dosage of antitoxin. For prophylaxis 1,500 units was usually given as a first injection intramuscularly; subsequently a dose of 500 units was injected once a week for three weeks.

For treatment an injection of 8,000 units was given by the intramuscular route together with 16,000 units intrathecally on the first and second days. On the two succeeding days this dose was halved, and on every second day afterwards 2,000 units was given by the subcutaneous route. Intravenous injection did not find favour owing to the danger of anaphylactic shock. The mortality fell from 58 per cent. in 1914 to 16 per cent. in 1917, and the period of incubation was raised from thirteen days to forty-seven days in the same period. Sir William Wheeler said he favoured large dosage; it was a case of toxin meeting antitoxin—a union took place, and the toxins were rendered inert.

Mr. W. DOOLIN recorded a case in which he had given 56,000 units intrathecally, intravenously, and intramuscularly with recovery. He drew attention to the fact that avertin had been very largely used in cases of tetanus in Germany recently in conjunction with antitetanic serum, with successful results.

Mr. H. STOKES thought the length of the incubation period might not have any relation to the severity of the disease, and mentioned the case of an officer during the war who contracted severe tetanus after a two and a half months' incubation period. He thought that the general opinion which had been formed during the war was that antitetanic serum in large doses had not very much advantage over that given in small doses. It was sometimes difficult to know when the infection had occurred.

Sir JOHN MOORE mentioned a case of tetanus at present under his care in hospital; the patient was recovering after the administration of 4,000 units only. Mr. F. J. HENRY said the only case of tetanus he had seen was one in which death occurred in a couple of days; the wound had been received from a cartridge fired from a toy pistol. In some cases Mr. Henry thought that the disease might be the result of acute infection from the patient's own intestinal tract. Mr. F. MORRIN referred to the advance in the successful treatment of tetanus which had been made by the use of avertin, and mentioned the cases of this disease which occurred in America every year after the celebration there of Independence Day and following wounds received from blank cartridges.

Persistence of Meckel's Diverticulum.

Mr. WILLIAM DOOLIN presented the case-histories of two male adults in whom the persistence of a Meckel's diverticulum was directly responsible for the condition of acute abdominal emergency.

A man, aged 44, was admitted to St. Vincent's Hospital with an inguinal hernia of three months' duration. At the operation the sac was found to contain a Meckel's diverticulum; this was reduced in the ordinary manner, and the sac was closed. Six days later, within two hours of dinner, the patient was suddenly seized with severe colic-like pain in the right abdomen and vomited once. The attacks of pain were rapidly intermittent, and an enema was returned heavily stained with blood. A tumour, dull on percussion, and tender to palpation, was found to be occupying the right flank. On the diagnosis of intussusception the abdomen was reopened; a large intussusception was found, its apex being within two inches of the hepatic flexure. As reduction proved impossible, the colon was rapidly mobilized, clamps were applied, and the colon was opened. The intracaecal mass of intussusception was amputated within the caecum, and the caecum was closed. The intussusception was caused by the inversion of the Meckel diverticulum, which, acting as an intestinal polypus, had produced an ileo-caecal intussusception. The patient made an excellent recovery, leaving hospital on the twenty-fourth day after operation.

The second case occurred in a man, aged 51, and was admitted to St. Vincent's Hospital as an "acute abdomen"; the patient's symptoms and physical signs pointed to the diagnosis of a subacute perforation of a duodenal ulcer. On opening the abdomen a heavily injected omentum presented, beneath which the coils of intestine were found to be covered with plastic lymph. Through the wall of one coil a piece of what appeared to be a quill projected. The complete coil was lifted out of the abdomen, when it was recognized as a Meckel's diverticulum; it was resected, and the opening in the bowel carefully closed. The patient made a rapid recovery, leaving hospital on the eighteenth day after operation. No histological examination of the diverticulum was made, as it was mounted as a unique museum specimen. The patient stated definitely after the operation that as he never ate fish the "quill" could not be a fishbone, but admitted that he had a habit of frequently plucking feathers from some hens he kept in order to use them as toothpicks; he often chewed these quills for long periods, and might have swallowed one unconsciously.

From a careful review of the available literature Mr. Doolin stated that perforation of a Meckel's diverticulum might be due to one of three pathological lesions: (1) peptic ulceration, in which the mucosa lining the diverticulum was of gastric type, and had ulcerated in the same fashion as gastric, duodenal, or jejunal mucosa might do; (2) inflammatory ulceration, either tuberculous or typhoid, and due to the involvement of the diverticulum, when present, in infections of the ileum; and (3) traumatic ulceration, due to the penetration of a foreign body from within the lumen of the diverticulum. The forecast in these cases varied greatly: the collective mortality of the peptic diverticular ulcers was over 50 per cent.; that of typhoid ulcers was 100 per cent.; in tuberculous ulceration the mortality was over 30 per cent.; and, in curious contrast, all the collected cases of purely traumatic perforation found in the literature (five in all) had terminated in recovery. Mr. Doolin asserted that the discovery of a Meckel diverticulum, whether the seat of pathological change or not, was sufficient indication for its removal. The method of removal might be either simple amputation or excision of the diverticulum along with its parent segment of bowel, followed by entero-anastomosis.

The PRESIDENT said he had never encountered a case of pathological Meckel's diverticulum. He had twice seen cases in anatomical subjects, but in neither instance was there any sign of pathological trouble having followed.

Mr. A. B. CLERY had recently discovered three cases of Meckel's diverticulum, the first in association with intussusception, the second causing acute peritonitis, and the third causing intestinal obstruction. Mr. H. S. MEADE said he had encountered four cases of intussusception at operation. In the first case the diverticulum was about 4 inches long. The second was one of obstruction in which there was a band running from the tip of Meckel's diverticulum to the caecum. In the fourth case operation revealed a diverticulum about 5 inches long. Mr. Meade had seen about a dozen cases in the dissecting room, but he had never found one inflamed or associated with any pathological condition. Mr. C. MACAULEY said he had detected a Meckel's diverticulum in the course of a routine examination of the abdomen on several occasions, but had only twice found it to be the cause of acute emergency symptoms. The first patient was a boy, aged 12, who complained of pain mainly about the umbilicus, and at operation Meckel's diverticulum was found attached to the umbilicus. The boy recovered completely. The second case resembled the one described by Mr. Clery, and an operation for intestinal obstruction was performed, the pressure being due to a band. It was hard to determine where the torsion began and where it ended, but the diverticulum was undoubtedly twisted. It was excised, and the patient recovered.

ANTIBACTERIAL POTENCY OF THE BLOOD IN PREGNANCY.

AT a combined meeting of the Edinburgh Pathological Club and the Edinburgh Obstetrical Society there was read a joint communication by Drs. DOUGLAS MILLER and J. R. WHITTAKER, jun., entitled "A study of the bactericidal and bacterio-static property of the blood during pregnancy and the puerperium, and its relationship to the development and course of puerperal infection."

The authors referred in the first instance to the anomalous nature of the incidence of puerperal infection which not infrequently developed in cases in which delivery had been spontaneous and uncomplicated, while failing to occur in cases in which trauma and manipulation had made its appearance probable. Bacteriological and clinical evidence appeared to warrant the inference that puerperal sepsis could rarely be explained on the basis of an endogenous infection: on the other hand, it seemed possible that the occurrence of sepsis in cases in which there had been a minimum of interference might be related to an abnormally low degree of resistance on the part of the individual. To test the validity of this hypothesis it was decided to examine the bactericidal and bacterio-static property of the blood in a large series of pregnant and parturient women, the

method employed being that described by Wright, Colebrook, and Storer. Coincidentally, the test of skin sensitiveness to streptococcal toxin was employed in a number of cases, but was discontinued, partly because the results obtained were inconsistent, and partly because, although the result might indicate the possession or otherwise of substances antitoxic to streptococcal toxin, it was not in the same sense a measure of resistance on the part of the individual to the important local invasive potentiality as distinct from the toxin-producing property of the organism, a property which from anatomical considerations was of special importance in puerperal infection.

Details of the Investigations.

In the majority of their observations the authors had employed a twenty-four-hours broth culture of *Staphylococcus aureus*, diluted to 1 in 5,000; in practice it had been found convenient to examine specimens of blood in groups of six, all of which had been withdrawn simultaneously and tested with one inoculum of uniform density. The bactericidal and bacteriostatic property of the blood in a total of 396 individuals was examined. The first series of experiments was undertaken to determine whether such individual variation as might exist could be related to the incidence of pyrexia in the puerperium; this series comprised 229 healthy individuals, all of whom had experienced spontaneous uncomplicated labours, blood being withdrawn at or about the time of delivery. There were in this group 17 women who subsequently experienced febrile puerperia due to pelvic infection: in 14 of these the degree of antibacterial activity of the blood was lower than the average of the other members of the respective groups, while in 3 cases it was higher. An associated investigation was conducted with cases in which labour had been seriously complicated, and in which, from the amount of interference and extent of trauma, it appeared probable that serious sepsis would develop. Twelve such cases were investigated, each potentially septic case being grouped along with women who had experienced normal labours, the latter constituting a control. In eight of the twelve groups the antibacterial power of the blood was above the average; all these patients recovered, and in two instances the puerperium was afebrile. In one case no difference was noted; this patient recovered. In three cases the antibacterial power of the potentially septic patient was lower than the average; two of these patients died.

The next series of experiments was undertaken to determine, if possible, the factors on which variability in antibacterial property might depend, and comprised, in the first place, a comparison of the antibacterial property of the blood of pregnant as compared with non-pregnant individuals, and of the blood at various stages of pregnancy and the puerperium. The results obtained showed that there was a gradual increase in antibacterial activity as pregnancy advanced, which reached its maximum at or about the full term of pregnancy. The effect of labour itself was slight, if spontaneous and uncomplicated, but after delivery there was a rapid decline in antibacterial power, the curve falling sharply, so that about the tenth day of the puerperium the non-pregnant level was reached; thereafter there was a further temporary increase, which had disappeared by the twelfth week after parturition.

A further series of observations was made to determine the effect of certain clinical conditions on the antibacterial power of the blood. There appeared to be no difference in this respect between the parous and the nulliparous non-pregnant individual nor between the primigravid and the multigravid woman. Albuminuria of pregnancy appeared definitely to depress the resisting power to infection as measured in this way. An attempt was made to determine the influence of prolonged labour, of instrumental delivery, and of severe blood loss on antibacterial activity; although the findings were given with reserve because of the existence of associated factors such as anaesthesia and fatigue, the effect of which it was difficult to appraise, the impression had been gained that with these conditions a lowering of antibacterial power occurred.

The authors presented, in conclusion, the results of an inquiry into the extent to which changes in antibacterial activity might be related to variations in the leucocyte count, and in particular to the leucocytosis which normally occurred during pregnancy. Although there was a broad parallel between the degree of antibacterial activity and the leucocyte count the relationship of the one to the other was in certain respects inconsistent. Whereas with a low leucocyte count the authors had usually found a similarly low degree of antibacterial activity, a white count above the average was not so uniformly accompanied by a corresponding increase in antibacterial power. This applied more particularly to cases of infection, but had frequently been noted in the absence of any apparent disturbance of health. It was illustrated particularly in the rapidly increasing leucocytosis which occurred during labour without any corresponding accentuation in antibacterial activity. Furthermore, in groups of cases in which both had been examined simultaneously it had occasionally been found that no relationship obtained between the one and the other.

It appeared probable, therefore, that the accentuation of antibacterial activity which occurred during pregnancy could only partially be explained by the simultaneous increase in the leucocyte count, and was attributable to factors other than, or in addition to, a mere numerical increase in white cells. What precisely these factors were, and by what means they could be stimulated so as to increase resistance to infection, remained for further research to determine.

THE ETIOLOGY OF RHEUMATISM.

AT a meeting of the Brighton and Sussex Medico-Chirurgical Society on May 2nd, with Dr. DONALD HALL in the chair, Dr. F. E. GRAHAM-BONNALIE read a paper entitled "Some aspects of rheumatism."

Dr. Graham-Bonnalie suggested that one of the chief stumbling-blocks to the advance of knowledge of rheumatism, especially of arthritis, was the question of classification. Probably the best classification was that adopted by the Ministry of Health, but this did not help very much in discovering the etiology or in the treatment, since the successful treatment of most diseases depended upon a just appreciation of the etiological factors. The greater part of research work tended to show that rheumatism was of bacterial origin, but that it was not possible to ignore the biochemical side of the picture, for, though this was probably only the precipitating factor, there would appear to be some relation between acidosis or a low *p*H and the rheumatic tendency. If, for the sake of argument, it was admitted that rheumatism was due to an infecting organism, could it be divided into streptococcal and non-streptococcal types? If such a clear differentiation was possible, why was treatment not more successful? Dr. Graham-Bonnalie suggested that one reason for this was that the organism or its right strain had not been isolated. He thought it possible that the streptococcus might alter its serological properties according to its particular domicile for the time being, and therefore he did not believe in using a vaccine prepared from too pure a culture, but preferred to combine it with a stock vaccine. A further reason might be that a primary focus had not been eradicated, which focus was most likely to be connected with the teeth or tonsils. Apparently the bowel was not uncommonly a primary focus, but was probably more often, as was the gall-bladder, a secondary focus. He gave as other possible reasons for failure in treatment the presence of secondary foci; another factor which had to be taken into account was the sensitiveness of the patient to vaccines, due to the presence of these foci, or because too large doses were given at the outset, or because a reaction was not always recognized as such. It was not necessary to give large doses to produce improvement. On the contrary, the smaller the dose which produced good results the more efficacious the treatment was likely to be. In some patients where there was great sensitiveness and no localized focal sepsis could be found, improvement continued even if repeated small doses of the same strength had to be employed. An underdose was never wrong; an overdose, especially at the outset, might be disastrous in a case which was at all acute. Dr. Graham-Bonnalie said that in a series of fifty consecutive cases he had endeavoured to find some relation between signs and symptoms on the one hand and the pathological findings on the other, but with no great success. There seemed to be little doubt that of all the organisms isolated from rheumatic patients, whether from teeth, tonsils, or the bowel, the commonest seemed to be the *Streptococcus viridans*. In the speaker's opinion the problem of dental infection was not so difficult as it appeared to be, provided that all the factors were taken into consideration. He also thought that pyorrhoea probably played little part in the primary production of rheumatism, but it might be a potent cause of secondary infection of the tonsils or bowel. He had had several cases in which the same organism had been isolated from the teeth, tonsil, and bowel, and the patients had responded to vaccines prepared from the bowel.

Reviews.

THE MEDICAL ANNUAL, 1929.

The Medical Annual[1] for 1929 contains a thoroughgoing survey, valuable alike to the general practitioner, the specialist, and the laboratory worker, of the progress of medicine and the ancillary sciences in Europe and America during the past twelve months. The growing importance of endocrine products in medical treatment is reflected in the articles on therapeutics. Among the many therapeutic measures described, especially worthy of note are the use of sodium salicylate in encephalitis, of tolysin (a cinchonic acid derivative) in rheumatic infection, avertin in anaesthesia, synthalin and glukhorment in diabetes, and a chart of recipes for use in liver therapy.

Professor E. W. Hey Groves reviews the treatment of tuberculous spine in children, Sir William Wheeler makes a survey of other diseases and injuries of the spine, and Mr. Geoffrey Jefferson writes on spinal fractures. Dr. Henry Devine surveys medico-legal psychiatry, clinical psychiatry, and psychopathology, with special reference to the alcoholic subject; Professor Beckwith Whitehouse writes on labour and its complications, twilight sleep, the two active principles of the posterior lobe of the pituitary, trial labour, and the failed forceps case. Professor Dickson Wright describes advances of surgery in the Orient. The article on the surgery of the chest is particularly well illustrated. The annotations on new discoveries include a description of the pityrosporon of Malassez in dermatitis, and the new thumb sign in pyramidal tract disease.

The article on the conduct of post-mortem examinations in general practice for medico-legal purposes is complete, practical, and modern. Equally commendable are the articles on radium, radiotherapy, and phototherapy; the nature and use of lysozyme, an antibacterial body present in the tears and more effective than any antiseptic ordinarily used in ophthalmic practice; pulmonary asbestosis, Kümmell's disease, and the rheumatic lung. The article on encephalitis brings up to date the information given in previous years. The medico-legal aspects of practice are, as usual, adequately considered, and the volume contains notes on the workings of the new Coroners Act.

Especially stimulating are the articles dealing with matters of current controversy: the etiology of rheumatic fever, the validity of liver efficiency tests, the value of washing out the renal pelvis, the treatment of gastric ulcer, and the relative advantages of thyroxin and thyroid extract. A great deal of unnecessary repetition of experimental work would be avoided if research workers made a practice of consulting the *Medical Annual* for the last few years before undertaking what they believe to be new investigations. Important features of this year's issue are the presence of full bibliographical references, indexes of new appliances and drugs, and useful lists of addresses of public bodies, traders, spas, and hospitals. The volume is well printed and the illustrations are good.

[1] *The Medical Annual.* Forty-seventh year. Bristol: J. Wright and Sons, Ltd.; London: Simpkin, Marshall, Ltd. 1929. (Demy 8vo, pp. c + 610, 141 figures, 71 plates. 20s. net.)

HYDATID DISEASE.

CASES of hydatid disease are comparatively rare in these islands and on the Continent, although the statistics of large hospitals show a certain number annually. Any series of cases, therefore, that is large enough to enable general conclusions to be drawn is likely to come from the countries, such as Australia and South America, where the disease is common. A notable exception is in the work of Professor Dévé of Rouen, who, by careful observation and experiment during the last thirty years, has probably contributed more than anyone to our knowledge of the general pathology and clinical course of hydatid disease. His papers, however, are scattered in many French and Belgian journals, and are often difficult of access. Since the war a band of workers at the Walter and Eliza Hall Research Institute, Melbourne, has reviewed from all sides the problems of hydatid infestation, and in his book *Hydatid Disease*[2] Mr. HAROLD DEW gives a full account of present-day knowledge in regard to this disease.

What are the outstanding facts about hydatid disease? The dog is the usual definitive host of the taenia echinococcus, while sheep are the most frequent intermediate hosts. It is in places where dogs and sheep are closely associated that the disease is most rife. Infection in man may occur through ingesting contaminated water or vegetables, but more frequently by direct contact with dogs; infection in childhood is common. Prophylaxis is best carried out by preventing the access of dogs to the offal (livers and lungs) of slaughtered animals at abattoirs. The embryo, passed in the dog's excretion, is taken in by the alimentary tract and carried in the portal vein to the liver, where it usually lodges, 70 per cent. of hydatid cysts occurring in the liver. It may pass through the liver and heart and settle in the pulmonary capillaries, where about 10 per cent. of hydatids are found, or it may get through to the general circulation. At the site of lodgement there is a reaction on the part of the host's tissues of mononuclear and eosinophilic cells, and eventually the growing cyst is surrounded by a capsule of fibrous tissue derived from the host. The cyst itself differentiates into three portions; on the outside there is a laminated elastic hyaline membrane, carrying on its inner surface a cellular germinal layer and enclosing the crystal-clear hydatid fluid. In the germinal membrane small areas of cells show increased activity and form the brood capsules in which the embryonic elements or scolices develop. The scolices are provided with hooklets and are retractile; by rupture of the brood capsules they become free, and may be present in enormous numbers, constituting the hydatid sand found in the cyst fluid. The scolices, when ingested by the dog, grow into the tapeworm in its alimentary canal, and the cycle starts afresh. There is evidence, too, that an intermediate cycle may take place, and scolices may grow into fresh hydatid cysts. In this way recurrence of hydatid in the incision and general peritoneal dissemination may occur from spilling of scolices at operation, or from rupture of a liver hydatid into the peritoneal cavity—a secondary echinococcosis (Dévé). Experimentally, too, scolices injected into the vascular system can by embolism develop into hydatid cysts. This is not, however, of frequent occurrence clinically, but may follow rupture of a hydatid into a blood vessel.

A curious phenomenon, more frequent in man than in the herbivora, and, as Mr. Dew points out, more frequent in older cysts and those which are so situated as to be subject to trauma, is the formation of daughter, and even granddaughter, cysts which become free in the cavity of the mother cyst, and which may again produce brood capsules and scolices. The daughter cysts may be derived from cystic development of scolices, but usually are formed from portions of the germinal membrane separated by trauma. Trauma and the character of the tissue in which growth is taking place probably account for the peculiarities of hydatid disease in muscle and bone, where wide spread dissemination may occur in the muscle planes and in the trabeculae. Besides rupture, suppuration may occur; again, injury to the cyst or interference with its nutrition precedes infection. Cysts may die, the fluid being absorbed, the cyst contents degenerating and the cyst wall undergoing calcification. Besides the symptoms caused by the state of the cyst, pressure symptoms occur and haemorrhage may be caused by erosion of a blood vessel.

The host responds to the presence of the cyst by various immunity reactions which can be used in diagnosis. The eosinophilia, an absolute increase in the eosinophilic cells of the blood, is present in about 30 per cent. of the cases; evidence of specific precipitins occurs in 65 per cent.; deviation of the complement may be demonstrated with

[2] *Hydatid Disease.* By Harold R. Dew, M.B., B.S., F.R.C.S.(Eng.), F.A.C.S. Sydney: The Australasian Medical Publishing Company, Ltd. 1928. (Roy. 8vo, pp. 429; 87 figures. 27s. 6d. net.)

modern technique in 80 to 100 per cent., and a specific response to intradermal injection of sterile hydatid fluid in 90 to 95 per cent. of cases. The recent Melbourne Hospital figures show that not more than 5 per cent. of hydatid cases have been missed when the combined use is made of the complement fixation test and the intradermal (Casoni) test.

Two-thirds of Mr. Dew's book is devoted to the consideration of the symptoms, diagnosis, and treatment of hydatid disease of the different organs of the body. This part is admirably clear, and the various points are elucidated by illustrative cases. No medical treatment has been found efficacious, and aspiration is dangerous. The surgical technique is fully described. The cyst should be exposed by suitable and ample incision, and the wound packed off. An amount of formalin to produce a concentration of about 1 per cent. of the cyst contents is injected to kill the scolices. The cyst is then incised and its contents evacuated. The indications for drainage or for closing the cavity after filling it with saline are fully dealt with. The volume is produced by the Australasian Medical Publishing Company, who are to be congratulated upon the result. The type is clear, and the illustrations are well reproduced. Typographical errors are rare, though one occurs in the preface, and the textual reference to Fig. lxxxvi is given as lxxxv. Mr. Dew's book is fully documented with references to the literature of the subject, and is likely to be for a long time the standard work on hydatid disease in the English language.

Hydatid Cysts of the Lung in Children[2] by Dr. HERRERA VEGAS of Buenos Aires, is a monograph based on the author's personal observation of 50 cases in his hospital and private practice. The book starts with a general description of the taenia echinococcus and of the development of a hydatid cyst. This description follows conventional lines, and is based on Déré's writings. Primary infection of the lung usually takes place. In the author's series of 50 cases, 28 were in the right lung, 19 in the left, and 3 were infected in both lungs. In 11 cases cysts were present elsewhere in the body, and in 5 cases more than one cyst was present in the lung. The author concludes that the child is not infected until after weaning, and that a maximum of two years may elapse after infection of the lung before the cyst is revealed by clinical manifestations. He believes that first the clinical signs and then the *x* rays, are the principal means of diagnosing and localizing pulmonary cysts; but quotes with approval an aphorism of Lanari that the finest cysts seen by radiography have turned out to be sarcomas of the lung. He mentions the diagnostic methods derived from immunity reactions, but does not give them the value accorded to them by the Melbourne Hospital workers. Vegas believes that once the presence of a hydatid cyst is known it should be operated upon at the earliest possible moment. Puncture, whether merely exploratory or aspiratory, is attended by so much risk that it should be rejected as a means of treatment; open operation is the method of choice. The author discusses the indications for closing the lung and chest without drainage, and for marsupialization. Of his series of 50 cases, in 3 cure resulted by coughing up the cyst; 6 cases were lost sight of after diagnosis. The remaining 41 were operated upon, and 14 died—3 at the time of operation, 8 of bronchopneumonia, and the others of sepsis. Of 12 cases in which the cyst was evacuated and closed without drainage, 5 died; while of 30 cases in which marsupialization and drainage were carried out, 23 recovered. Some patients were operated upon twice. The book is unfortunately difficult to read, the spelling is often inaccurate, and sometimes the meaning is only clear from the context. The case sheets of the author's 50 patients are full of detail, and there is an excellent bibliography of Argentine and foreign literature. In the compilation of the latter, the author gratefully acknowledges the assistance received from the officials of the Royal Society of Medicine, London.

[2] *Hydatid Cysts of the Lung in Children.* By Marcelino Herrera Vegas, M.D., F.A.C.S., F.R.S.M. Buenos Aires: S. A. Imprenta Lamb y Cía, Ltd. 1927. (Sup. roy. 8vo, pp. 300; illustrated.)

CONGENITAL SYPHILIS IN THE NEWBORN.

OLUF THOMSEN'S atlas of pathological changes in congenital syphilis in the newly born[4] was first published in Danish in 1912. It now appears in German, and so will be available to a larger number of readers. This monograph provides for the student of syphilis in the newly born an atlas of illustrations of the most commonly found manifestations. The wide distribution of syphilitic infection in the foetus is readily appreciated from them. The illustrations have been selected from a series of 223 cases of congenital syphilis which the author has examined. The author in the preface points out as a justification for this book the gradual disappearance of grosser manifestations of syphilis since the recognition of the *Spirochaeta pallida*, and the introduction of the Wassermann reaction and salvarsan treatment.

There are about twenty pages of text. The author has made a comprehensive and exhaustive investigation into the problem of mode of infection of the foetus: he believes that everything speaks against a germinal route of infection and that the placental is the only proved route. He investigated forty-two cases of abortion before the third month, and only two of his cases had evidence of syphilis. Further, he examined the products of abortion of six known syphilitics, and in only one (a 5 months foetus, maternal Wassermann reaction positive) was the *Spirochaeta pallida* found. Thomsen has also investigated twenty-seven 6 months syphilitic foetuses, and in only three has he found syphilitic manifestations. The conclusions Thomsen reached from this extensive personal investigation was that histological examination of the foetus during the first five months showed no evidence of syphilis—if the infection is a germinal one it must remain passive in the first half of pregnancy, a most improbable occurrence. The ground of failure to find either spirochaetes or anatomical changes is, in his opinion, because syphilis is transmitted through the placenta, which first towards the middle of pregnancy is passable. He believes the placental "age changes" render it passable. Although he has been unable to find a spirochaete passing through a placental villus, he lays little stress on this negative finding, and all who have investigated syphilitic placentas will agree with him.

The book is attractive on account of the lucidity with which the subject is presented. It forms a notable contribution to the subject of congenital syphilis.

PHYSIOTHERAPY.

THE second edition of *Physiotherapy*[5] by Dr. HARRY EATON STEWART shows evidence of careful revision and of the degree of enlargement warranted by the growing importance of this subject in everyday practice. An outstanding merit in all Dr. Stewart's writings is the modesty of his claims. He is not one of those who see in physiotherapeutics a cure for every ailment. He aims rather at explaining in simple language the physiological responses that may reasonably be expected from the various forms of treatment. He considers that the time is now ripe for the general practitioner "to be familiar with the physics, physiological effects, indications, and contraindications of the various physiotherapy modalities." The rapid growth of actinotherapy in this country shows clearly that the practitioner is ready to make himself familiar with the care and use of apparatus which he believes will give him results that he could not obtain by the older and more familiar forms of treatment. In the present edition the new field opened by the so-called endothermy current, and so capably explored by Dr. Harvey Cushing, is dealt with; but the chapter that describes this current would have been improved by further details, particularly as regards its uses and limitations.

The author states in his introduction that "many industrial insurance companies are either making contacts

[4] *Pathologisch-Anatomische Veränderungen über die congenitale syphilis bei dem Foetus und dem Neugeborenen Kind.* Von Oluf Thomsen. Copenhagen: Levin and Munksgaard; Leipzig: G. Thieme. 1928. (Demy 4to, pp. 31; 19 plates.)

[5] *Physiotherapy.* By Harry Eaton Stewart, M.D. Second edition, revised. London: Milford, Oxford University Press. 1929. (Med. 8vo, pp. xvii + 365; 76 figures. 35s. net.)

with established physiotherapeutic clinics or establishing their own. The saving is calculated upon the provisional award made for a given disability. After a regime of treatment the reduction of award minus the cost of the treatment constitutes the net saving in the case. It is solely on this financial basis that physiotherapy must demonstrate its value to the companies. There must be a reduction in the amount of weekly compensation paid and a lessening or elimination of the partial permanent disability greater than the cost of physiotherapy treatment." No better evidence that properly run physiotherapeutic clinics "deliver the goods" can be given than this; and it would be interesting if an English industrial insurance company were to make an experiment on these lines. If the results showed definite shortening of the period of disability, they would afford valuable statistical proof of some of the claims of physiotherapeutic specialists and help to remove some of the scepticism with which their methods are at present viewed.

Although Dr. Stewart has written another book on the uses of diathermy with special reference to pneumonia, it is satisfactory to find that in the book under review he has made an excellent précis of his experiences in the treatment of broncho-pneumonia and lobar pneumonia. His candid statements with regard to the cases in which diathermy has failed, and his explanation of the technique and clinical responses to be expected in pneumonia, alone make the book worth reading.

INJECTION TREATMENT OF VARICOSE VEINS.

THE influence of the late Professor Sicard on the development of the treatment of varicose veins by sclerosing injections is well known, and his commendation in a prefatory note of a little practical book[6] by Dr. RAYMOND TOURNAY will go far to popularize a useful handbook for those who read French. After discussing briefly the history of the treatment of varicose veins, their etiology, and symptomatology, Dr. Tournay gives a careful account of the injection treatment, including the possible difficulties and the ways of overcoming them. He then deals with such complications of this condition as eczema and ulceration, and also with the application of the injection treatment to such morbid processes as angioma, haemorrhoids, and varicocele. A few illustrations emphasize usefully various points in the technique. The book will, doubtless, win favour as a methodical statement of this treatment from the purely practical point of view.

A fourth edition of Dr. A. H. DOUTHWAITE'S popular book *The Injection Treatment of Varicose Veins*[7] has now appeared; the third edition was noticed in our columns on June 23rd last. The principal additions refer to the injection of varicocele, the use of Dalton's carbolic acid method, and the dangers arising from the employment of incorrect technique in the obliteration of varices.

NOTES ON BOOKS.

THE third edition of KOLLE and v. WASSERMANN'S handbook of micro-organisms[8] is appearing seriatim. We mentioned the publication of previous fasciculi in our issues of May 7th, 1927 (p. 839), February 11th, 1928 (p. 223), and October 27th, 1923 (p. 751). Seven further fasciculi have reached us—namely, Part 29 of vol. i, in which the subjects of allergy, anaphylaxis, and the relation of colloids to the immunization process are reviewed; Parts 23 and 24 of vol. iii, dealing with serological, chemotherapeutical, and epidemiological topics; Part 25 of vol. v, which is largely concerned with leprosy; Parts 27 and 28 of vol. vi, containing numerous articles on bacteriological and worm infections; and Part 26 of vol. ix, which is devoted to certain veterinary and botanical diseases. The high standard of the previous volumes is well maintained.

Practical parasitology,[9] as its name implies, is essentially a handbook for use in classes of human parasitology. Most of the parasites and their vectors encountered in the ordinary course are discussed, and brief notes are given on their biology and pathogenicity. In addition to the protozoa, helminths, and arthropods, chapters are included on the spirochaetes, fungi, intermediate hosts, and on technique. There are numerous black-and-white illustrations, all of them full-page size and well reproduced. The volume is excellently written, in easy French, by two well-known authorities and teachers, and it is published at a very low price. It will prove an invaluable laboratory companion to all students of the subject.

In ancient times philosophers expatiated on morals, and sought after absolute goodness, truth, and beauty. The discoveries of science, however, have compelled them to take cognizance of human development and structure; hence the numerous attempts to reconcile science, philosophy, and religion. Of such efforts, *From the Seen to the Unseen*,[10] by the Rev. J. H. BEST, vicar of Little Marlow, is certainly one of the most readable. Mr. Best has read much; he possesses an extensive knowledge of science, and he is clear in exposition. His object is to prove the existence of purpose, and with relentless purpose he expounds the purposeful aims of Providence in the development of man. We are led through the pathways of physiology, embryology, psychology, evolution, and astronomy with the idea that they all lead to the goal of conviction that man is the highest product of the Divine Mind. Religion would appear, from Mr. Best's arguments, to involve a kind of spiritual anthropomorphism. As the world is beautiful, we must attribute to the Divine Mind which designed it a feeling for beauty. So that the Divine Mind not only possesses intelligence and will, but also, like the human mind, is susceptible to emotion. Mr. Best believes that in every germ cell there is a "psyche," which in some way is part and parcel of the Divine Mind, and he argues skilfully that only on some such assumption can memory be explained. In fact, his chapter on memory, and his exposition of the weak points in theories that seek to explain evolution, from the pangenesis of Darwin to the latest views on Mendelism, are among the cleverest things in the book. Towards the end, however, when Mr. Best begins to resume the role of clergyman, and much poetry creeps into his text, he may be found less convincing. To the minds of some the attempt to solve insoluble problems brings satisfaction. Others can only sum up their experiences by saying that they "came out by the same door as in they went."

Our Tounis College[11] is a collection of verses published in the students' magazines of Edinburgh University during the last century. The Students' Representative Council is responsible for the production of the volume, and most of the selections are verses by undergraduates that were published in *The Student*. Some of the verses bear well-known names, and especial mention must be made of those by the late Professor Mair. Among these is his famous Greek rendering of the song "Clementine," in which the rhythms of the original are carefully preserved in the Greek. In a different vein is his beautiful lament for the vanished students, which was written in 1917. The real interest in the volume lies, however, in the average verse that it contains—verse which records the thoughts of youth for a century, sometimes cynical, sometimes sentimental, usually critical, changing with the changing generations, and yet always touched with the same enthusiasm and energy. Most readers will find much to interest and amuse them in this volume, but it will, of course, appeal specially to that great band that is scattered over the five continents, the Edinburgh alumni. The Students' Representative Council and its editors are to be congratulated on having rescued from oblivion this interesting record of student thought.

In the *Writers' and Artists' Year Book, 1929*,[12] those who are interested in the press as a market for their literary, artistic, musical, or photographic works will find much useful information. The main feature is a directory of British and American publications, with notes on their requirements and scales of payment. Advice is also given on questions of copyright, publishers' agreements, etc.

The British Goat Society's Year Book for 1929[13] contains, in addition to articles and poems in praise of the goat—which, as

shown in many of the photographs adorning the volume, is a most praiseworthy animal—a number of papers of medical and veterinary interest, and articles and memorandums dealing with the problems, scientific and economic, of goat keeping and goat breeding. This, the ninth issue of the *Year Book*, is admirably produced and illustrated, and contains much interesting and useful material.

Two volumes of reprints of papers and monographs by members of the gynaecological department of the Johns Hopkins Hospital and University have been issued,[14] the first containing those published from 1922 to 1926, and the second volume those from 1926 to 1928. They have been placed in the Library of the British Medical Association, where they can be consulted by members.

A volume of reprints of researches emanating from the wards and laboratories of the London Hospital during 1928[15] has been published by Messrs. H. K. Lewis and Co., Ltd. It includes the Schorstein Lecture on expectoration, various clinical reports, and physiological and pathological articles.

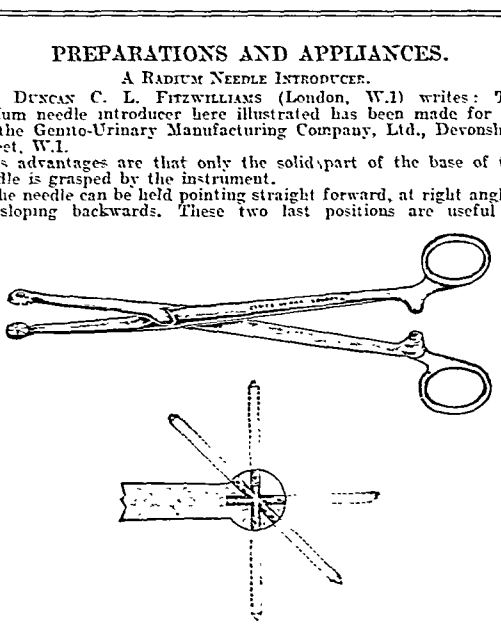
PREPARATIONS AND APPLIANCES.

A Radium Needle Introducer.

Mr. Duncan C. L. Fitzwilliams (London, W.1) writes: The radium needle introducer here illustrated has been made for me by the Genito-Urinary Manufacturing Company, Ltd., Devonshire Street, W.1.

Its advantages are that only the solid part of the base of the needle is grasped by the instrument.

The needle can be held pointing straight forward, at right angles, or sloping backwards. These two last positions are useful in

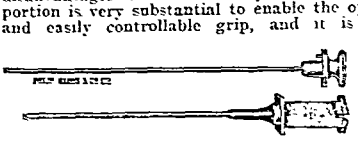


dealing with tumours in positions like the base of the tongue. There is a cuplike depression on the outer side of the forceps, which facilitates pushing the needle into the tissues flush with the surface.

The handles vary in length according to what is required of the instrument. They should be at least 8 inches long; this keeps the hand well away from the radium, and also allows needles to be inserted through a proctoscope or a short sigmoidoscope.

A Maxillary Antral Trochar.

Mr. B. Seymour Jones, F.R.C.S., honorary surgeon, Ear and Throat Hospital, Birmingham, writes: The maxillary antral trochar illustrated has been designed to overcome some of the disadvantages of the ordinary Lichwitz pattern. The proximal portion is very substantial to enable the operator to obtain a firm and easily controllable grip, and it is slotted for a bayonet catch on the male attachment. This modification was devised because a nurse at the Ear and Throat Hospital contracted a temporary ophthalmia owing to some pus being splashed into her eye when she was using an ordinary push-in attachment. A fluting on the side of the butt of the trochar corresponds with the point of the bevelled end of the hollow needle, which should always be directed outwards to the bone. A special adapter (not shown) is supplied, which fits a Watson Williams's syringe. Solutions such as argyrol 5 per cent. (Tilley) or iodoform water (Seymour Jones) may thereby be introduced with great benefit into an acute suppurating antrum.



ATHLETICS AND TRAINING.

The following note on a recently published book has been contributed at our request by Mr. E. B. Turner, F.R.C.S., vice-president (president in 1913) of the London Athletic Club.

All those who actually compete in athletics, as well as those who take an interest in such sports, will be well advised to read and study *Athletics*,[1] by Mr. D. G. A. Lowe and Dr. A. E. Porritt. Both these gentlemen have been presidents, the one of the Cambridge, the other of the Oxford University Athletic Club. Both also are record holders—in one case of a world's record—and both of them have represented their country in the Olympic Games. Lowe achieved the unprecedented feat of winning the 800 metres race at two successive Olympiads, and Porritt reached the final of the 100 metres, running fourth against the cream of the world's talent. Both authors, therefore, are thoroughly well qualified by hard-earned personal experience to treat of this matter with knowledge and authority. In this book they have given a history of athletic competitions from the very earliest times—from the Funeral Games for Patroclos up to and including the 1928 Olympiad. This chapter alone is well worth attentive study.

After their historical opening the authors proceed to discuss the most important and essential subject of training. They deal with this difficult question with skill and discretion. No hard-and-fast rules are set forth as the laws of the Medes and Persians. Moderation in all things is the keynote. They do not argue from the individual to the mass, but advise that each person, having found out what may suit himself best in food, drink, sleep, and exercise, should stick to that regimen and so attain the greatest possible perfection in bodily condition. They rightly insist that all training should be gradual and progressive, and that no person really unsound should ever attempt to take part in strenuous athletic competitions. Hints are given with regard to the proper training which is necessary to get fit for short and long distance racing, hurdling, cross-country running, high and long jumping, as well as the various field competitions, such as putting the shot, hammer, discus, and javelin throwing. The aid of such experts as C. T. van Geyzel and M. C. Nokes in high jumping and hammer throwing has been invoked to make the chapters on these events full and authoritative.

There is a section devoted to athletics for women and boys. The unwisdom of allowing young growing boys to overdo competitions is insisted on most strongly, and all those who know anything about the physical and mental effects of strenuous competitions will most heartily agree. The authors face the fact that athletic competitions for women have come to stay, though they evidently do not thoroughly approve of it on aesthetic and other grounds. The commission which went into the whole question of strenuous games for women some years ago, after hearing exhaustive evidence, unanimously reported in favour of such games; and the great experience of Dr. Sanderson Clow with some 2,000 girls at Cheltenham shows that hard exercise at all times improves the health of the girl. The women who race in the present day have been well coached and trained, and on a side view show as good and elegant form as the majority of men. The Women's Amateur Athletic Association is directing this very important movement with great circumspection, and those of the medical profession who really understand athletics have found no harmful effects on those women who compete with discretion, while the good effects of hard open-air exercise and training on hundreds of "indoor" girls are apparent.

The book contains an appendix of tables of records and statistics which are most interesting, especially to anyone who may have been fortunate enough to see most of those which were achieved in England. One or two errors have crept in. For instance, C. N. Jackson ("Jacker") of Oxford University was credited with 16 seconds for the 120-yards hurdle race in the late sixties. This record may or may not be one which would be accepted at the present time, but it has always been set forth in the tables of the Oxford and Cambridge sports. M. J. Brooks is credited

[1] *Athletics.* By D. G. A. Lowe and A. E. Porritt. London and New York: Longmans, Green and Co. 1929. (Demy 8vo, pp. x + 372; 39 figures. 12s. 6d. net.)

with the 6 ft. he cleared in pouring rain on wet grass in the A.A.C. championships in 1876, but not with the 6 ft. 2½ in. which he jumped on the preceding Friday at the Oxford and Cambridge meeting. The initials of the Eton schoolboy, Ridley, who won the 440 yards in 1868, were "J. H.," not "E."

One great thing about this book is that, even in these days of keen rivalry, it nowhere puts the actual "win" first of all. It is easy for any young athlete studying this excellent book still to appreciate the great fact that "the training is more than the contest, and the contest more than the win."

INTERNATIONAL CONGRESS OF MILITARY MEDICINE AND PHARMACY.

LONDON, MAY 6TH TO 11TH, 1929.

THE fifth International Congress of Military Medicine, the earlier proceedings of which were reported in our last issue, concluded on May 11th, amid many expressions of congratulation. It was decided at the closing meeting to drop the pendant "and Pharmacy," the term "Medicine" being judged sufficiently comprehensive. It cannot be said that the discussions revealed anything very novel; perhaps the newest thing was a suggestion by a Spanish delegate, made in the closing hour of the Congress, for an international standardized form of register, giving the clinical history and all other particulars, in each case of sickness or injury. The fraternal feeling encouraged by the Congress was evident on all sides and highly gratifying.

LORD MOYNIHAN'S ORATION.

The entertainment given by the Corporation of the City of London in the Guildhall was in a sense the climax of the Congress, 770 being accommodated at the banqueting tables. In addition to the Lord Mayor, the aldermen, and commoners, and the delegates and members of the Congress, [illegible] included the Chief of the Imperial General [illegible] of the Royal Colleges, the Vice- [illegible] dozen universities, representatives of Government departments and other official bodies, and the presidents of medical societies, including the British Medical Association. A noteworthy oration was made by Lord Moynihan, President of the Royal College of Surgeons, in proposing the toast of the evening.

Lord MOYNIHAN spoke as follows.

It is entirely right that we medical men should have our day of celebration after a great war, for we above all men know what the cruelties and cruelties of war have always been and still remain, and we—not more than all men, but with more reason than others—have a detestation of war in all its aspects. I shall never forget my first few days' experience of its revolting tragedies. Within one minute I saw more destruction of life than I have ever been able to prevent in a year of arduous work. I think it may interest some of you if I recall the effectiveness of our army in France in respect of its medical services during the great war:

Total wounded	1,983,748	
Wounded returned to duty	1,602,033	(80.7%)
Total sick	3,494,165	
Sick returned to duty	3,260,056	(93.3%)
Sick and wounded returned to duty ...	4,862,089	

If the average strength of an army is roughly 288,000 men, the medical services were responsible for returning to duty no less than 16.8 full armies. But a great claim may also be made on behalf of the medical services of all countries with regard to their help in times of peace. Here we see, to as great a degree as we see anywhere, an evidence of the brotherhood of science. The men attached to the medical services of the various armies have been responsible for work which in times of peace has saved scores of millions of human lives. Take the problem of malaria, the parasite discovered by Laveran of France, and the agency of the mosquito in transmission demonstrated by our own Ronald Ross and by the illustrious Grassi of Italy, and here we have a triple entente—England, France, and Italy—engaged in another form of warfare against the enemies, not of one nation, but of mankind. We recall with gratitude the work on inoculation by Almroth Wright. Though the war in France lasted much longer than the South African war, and a larger army was employed, fewer men suffered from typhoid fever in the war in France than died from it in South Africa. The incidence of typhoid in the inoculated was one-tenth of the incidence in the uninoculated, and the case mortality in the latter was four times greater than in the former. I think it is true to claim for Almroth Wright and for Leishman that their work saved an army corps for the British army in France. Another piece of work in the late war was the attack on bilharzia. It has been shown that bilharzia has affected the population of Egypt since the days of the Pharaohs. The parasite was discovered by a German, Biharz—may I express my personal regret that no German is with us to-night—and the secret of the transmission was worked out in part by a Japanese and in part by Leiper in England—again a triple association of nations to the advantage of mankind as a whole. Also I want to carry the recognition into military work of our immense debt of obligation to the nurses. The most illustrious name in the whole history of warfare from the beginning of time is the name of Florence Nightingale.

Well, my Lord Mayor and brother officers, if there is any meaning behind life, if life is not merely a feast, or a spectacle, or a predicament, but is, as I believe, a sacrament, we must be sent into the world for the purpose of helping each other. It is because our profession in all its activities is founded upon the law of love, love to one's fellows, love to mankind, expressing itself in service, that I ask you to drink to the success of the present Congress.

Three brief responses were made—in French by General LANNE, in Italian by General RIVA, and in English by Colonel G. E. SEAMAN of the United States, who took the place of Surgeon-General Cumming. Sir HUMPHRY ROLLESTON proposed the health of the Lord Mayor and Corporation, and spoke of the traditions of civic London, its administrative stability, its princely hospitality, its generous charities, its wise endowment of research. He also paid a tribute to Sir Kynaston Studd, not only as Lord Mayor, but as a son of Cambridge. With the Lord Mayor's very sincere and informal reply the proceedings were brought to a close.

DISCUSSIONS.

Tropical Fevers of Short Duration.

On Thursday morning the Congress devoted itself to a discussion on tropical fevers of short duration, General LANNE, presiding. Lieut.-Colonel W. P. MACARTHUR introduced the subject with a paper, in which he said that diseases might be indefinite because they were typical examples of well-known infections, or because they were separate clinical entities which still awaited full description. The first class included mild or abortive cases of typhoid, paratyphoid, and undulant fever. Malaria frequently showed a low continued fever, the paroxysms being absent and the parasites so scanty in the blood as to be easily overlooked. Dengue and phlebotomus fever were recognized as distinct clinical entities, but owing to the lack of definite symptoms were frequently confused with similar syndromes. Especially was this the case with influenza, which was very common in the tropics, but rarely accompanied by nasal catarrh. The blood pictures of dengue and sandfly fever were often not sufficiently distinct from that of influenza to separate, with certainty, these diseases. Recently spirochaetosis as a cause of short fever had attracted attention. The leptospira as a group showed many variants, which, although indistinguishable morphologically, yet seemed able to cause clinical symptoms which varied from a day or two of pyrexia up to a severe toxaemic jaundice. Weil's disease had probably at times been recorded as dengue. The more severe forms of dengue disease, in its turn, could generally be distinguished from spirochaetosis by their respective blood pictures. Weil's disease, in its turn, could generally be distinguished from yellow fever by the relative quantities of albumin in the urine. Colonel MacArthur added that the attempts which were being made to classify and describe indefinite short fevers were handicapped, and confusion increased, by the habit of labelling cases, in which the diagnosis was really unknown, with a definite name, for the sake of hospital records. If a case, in spite of all investigation, remained a "pyrexia of unknown origin," it must be honestly left as such in all sick returns.

M. GERARDS (Dutch East Indies) said that febrile diseases of the tropics, formerly differentiated by clinical manifestations alone, could [illegible] ation as a manner. Duration and [illegible] tion of the means of identification had given place to detection of the

causative organism, so that a rational system of classification and a better nomenclature were now possible. He proceeded to give a précis of the more important diseases of the group, including yellow fever, Weil's disease and other spirochaetoses, and dengue and its group of diseases.

Short communications were made by MM. SACQUEPÉE and CRISTAO (France) on tropical fevers in the Mediterranean littoral, by Colonel CAZANOVE on these conditions in the French colonies, and by M. BLANCHARD, who spoke of the African epidemic icterogenic spirochaetosis, a disease described by him and other French observers, resembling yellow fever and Weil's disease, capable of transmission by *Aedes argenteus*, and spread by fleas.

Dr. A. CAWADIAS (Greece) spoke of the epidemic of dengue fever occurring lately in South-Eastern Europe. When in Greece some time ago he found certain small epidemics of dengue fever, and from these small epidemics there had now developed a very serious epidemic in the Eastern Mediterranean. *The epidemiology of this condition* needed to be studied, and this was the task of a commission now in Greece. Dengue fever was due to a virus circulating in the blood; the exclusive carrier was *Aedes argenteus*. He thought there were many cases of so-called three-day fever which were really dengue. This was a benign condition, and did not kill, although, if the patient was suffering from some concurrent malady it might hasten a fatal termination.

Injuries to Blood Vessels.

The third subject of discussion at the Congress was injuries to blood vessels and their sequels. It was opened by Surgeon Commander H. E. R. STEPHENS, who read a joint paper by himself and Colonel G. DE LA COUR. He made *grateful acknowledgement—as did several of the subsequent speakers*—of the indebtedness of all workers in this field to Sir George Makins (who was on the platform) for his contributions to the general knowledge during the war. Perhaps the point of chief importance in an exhaustive paper was as to the treatment of primary and secondary haemorrhage. In the local treatment of primary haemorrhage blood vessels in the open wound were ligatured as early as possible. When an injured vessel was visible in an open wound it should be ligatured whether bleeding or not, and a thrombosed vessel should be treated in a similar manner to avoid a degree of secondary haemorrhage. It was inadvisable to interfere primarily with a large vessel which had been wounded in the course of a track traversing the body or limbs if no signs of haemorrhage were forthcoming, or if there were no indications that the vitality of the distal portion of the limb was being endangered, but the formation of traumatic aneurysm should be awaited. As for general treatment, in sudden and abundant primary haemorrhage immediate blood transfusion was indicated. In less severe cases Bayliss's gum arabic solution might be tried, followed later by blood transfusion if necessary. *In mild cases administration of* fluids by mouth and rectum might be made, followed by the other measures if expedient. In the local treatment of secondary haemorrhage direct ligature of the bleeding point was the only satisfactory practice. Proximal ligature, except for the gluteal and sciatic arteries, was unreliable; in the general treatment immediate transfusion of blood provided the safest course. The authors set forth the following as a guide towards perfecting the special surgical technique required in performing suture of the vessels:

Lateral wounds involving not more than one-third of the calibre of the vessels are most suitable for suture. If more than one-third of the calibre is injured then an end-to-end union is attempted after resection of the damaged segment.

Reconstruction of a vessel by employing flaps from the adventitious sac of an aneurysm is not advised.

Very fine needles with Japanese silk—size 0000—*which has been* coated with paraffin will enable the best results to be obtained.

The most satisfactory arteries for suture are the carotid, the femoral, and the popliteal.

Colonel MAISONNET (France) stated objections to improvised tourniquets. He said that in all countries efforts were being made to produce a perfect tourniquet for field use. All combatants should be trained in the method of application. Every wounded man to whom a tourniquet had been applied should be specially reported and evacuated as soon as possible to a surgical unit. The treatment of blood vessels had benefited greatly by the general improvement in the treatment of war wounds, and the prognosis had improved with the facilities for early and more elaborate treatment in the surgical organization of the army.

Major VONCKEN (Belgium) spoke of the sequels of wounds of the blood vessels, and discussed the trophic, vasomotor, and functional causes to which delay in the restoration of the circulation might be due. The formation of arterial and arterio-venous aneurysms, diffused or cirsoid haematomas, constituted grave complications in wounds of blood vessels. In general, the treatment most frequently applicable was resection, in addition to ligatures required during the operation. The after-effects of wounds of blood vessels were important, and even in the absence of visible disturbances the function must be watched very closely by means of the passive movement test and oscillometric research.

A very large number of speakers, the great majority of them from France, took part in the discussion. Colonel LÉO paid a tribute on behalf of his French colleagues to Sir George Makins. He also described a case in which a missile pushed the wall of the artery to one side and produced a clot. Professor CACCIA (Italy) related his personal experiences of wounds of the blood vessels during the great war. He believed that injuries to blood vessels caused by bullets were less grave and healed more quickly than those produced by shells. The greatest number of injuries to blood vessels were in the extremities, especially the lower limbs. The tourniquet in wounds of vessels in war increased the chance of gangrene, and should be avoided, or at least maintained for the shortest time possible—not more than one or two hours. Lieutenant WALCHER (France) spoke on the operative technique in aneurysms, Dr. LATKOWSKI (Poland) urged the suture in replacement of the tourniquet, Colonel GOMEZ (Spain) exhibited some absorbable metallic sutures of his own devising, Dr. FRANCESCO (Italy) dealt with the immediate and remote effects of aneurysms, Colonel BOTREAU-ROUSSEL (France) described the results after the use of a triple ligature, and also of resection in a case of popliteal aneurysm, Dr. STABHOLZ (Poland) remarked on the surgical treatment of aneurysms, as did Colonel LEVIT (Czechoslovakia), while Dr. ZAHOUB, Dr. FREDER, Colonel DE FOURMESTRAUX, and Professor JEANNENEY, all of France, spoke generally on *dry wounds of blood vessels*.

The discussion may be summarized in the "conclusions" brought forward at a later stage.

The immediate danger of wounds of the blood vessels is considerable, and mortality higher in war wounds than in peace-time injuries. Wounds of blood vessels require treatment to be carried out as soon as the wound is inflicted. In spite of its drawbacks the tourniquet is essential. Efforts to devise a simple and effective tourniquet which is not dangerous are necessary.

The surgical treatment is not straightforward. In most cases ligature is necessary owing to the nature of the lesions and their association with other wounds. It is necessary to have thorough access and to employ methods which will produce the most satisfactory restoration of circulation and function.

The ultimate prognosis is reserved. It depends on sequelae: (1) deficient circulation with its various signs—trophic, functional, and vasomotor disturbances; (2) aneurysms. Prognosis may be improved by treatment of these after-effects. Treatment of functional disturbances is still being investigated. *Treatment of aneurysms generally* consists in resection of the part of the sac with necessary ligatures. Secondary operations, such as suture of blood vessels, are seldom applicable in military surgery. The after-effects must not be lost sight of when *fixing* the percentage of disability for injuries to the blood vessels.

Standard of Dental Fitness.

At a meeting of the Congress held at the house of the *British Dental Association*, a communication on the state of the teeth in relation to physical fitness in the different military services was made by Surgeon Lieut.-Commander J. T. WOOD, Captain S. H. WOODS of the Army Dental Corps, and Lieut.-Colonel C. L. COLBRAN. They gave the following comparative figures of percentage rejections for purely dental reasons in the three services:

	Navy.	Army.	Air Force.
1924	4.57	3.8	6.7
1925	5.12	3.3	5.9
1926	6.10	3.4	6.9

They also noted that closed dental sepsis producing severe systemic lesions had followed the conservation (frequently by crowning) of pulpless teeth. The recognition by the dental profession to-day of the uncertainty of the result of the treatment of infected teeth and the grave symptoms which so frequently followed such treatment would, it was to be hoped, result in fewer cases being recorded in future of the effects of closed dental infections.

Captain CLARK (Cuba) gave an account of the dental service in the Cuban army, which, he said, had been gradually perfected until it possessed in each district, even the remotest from the capital, dental surgeries inferior to none, where dental practitioners could do their work effectively.

The result of a considerable discussion may be summed up in the "conclusion" presented to the meeting:

"There is a definite relationship between dental conditions and physical efficiency. A high standard of dental function should be required for admission to the fighting services, and adequate provision should be made for maintaining this standard. In countries where military service is compulsory the period of such service should be utilized for the continuance of prophylactic treatment in dental hygiene."

Testing of Glass and Rubber.

A discussion also took place at the house of the Pharmaceutical Society on the physical and chemical analysis of the glass and rubber articles employed by the medical services, when Surgeon Commander F. LEWIS SMITH and Mr. F. HOOPER, technical assistant to the Medical Director-General of the Navy, presented a paper describing the available tests. They mentioned that rubber was the most difficult of all articles used in the profession so far as satisfactory testing was concerned; but they described certain simple tests which yielded satisfactory results for the medical storekeeper. A more comprehensive paper on the same subject was presented by the Spanish delegation.

CLOSING MEETING OF CONGRESS.

The closing meeting of the Congress was held on Saturday morning in the Great Hall of the British Medical Association. The chief business was the reading, in four languages—English, French, Italian, and Spanish—of the "conclusions" of the week's discussions. These were not in the form of resolutions, but were summaries by the committee of the Congress of the leading points which had emerged.

A belated communication from Dr. TUFFIER of Paris was read by Air Vice-Marshal MUNRO. The subject was the use of aeroplanes for the transport of surgical cases, which had been the first subject for discussion by the Congress. Dr. Tuffier was of opinion that the fighting plane could be transformed readily into a machine for the transport of the wounded. For general use a saloon de luxe was not required; the conditions were that the machine should be warm and airtight and should contain all that was necessary for the duration of the flight. There was no more danger in flying, even to the most serious surgical case, than in undergoing a general anaesthetic. He did not think, however, that evacuations by aeroplane could be made on a very big scale. The slightly wounded should be otherwise transported. He made some practical suggestions as to the use of injections before starting, in order to avert as far as possible any unfortunate consequences to the patient.

International Standardization.

Colonel VAN BAUMBERGHEN (Spain) reported on certain resolutions which were taken at the session of the Committee on Standardization of the International Red Cross Organization at its meeting in July last. Statistical tables (of which he showed examples) had been devised with a view to forming a continuous record of each case of injury or sickness in a form and with a nomenclature applicable to all countries. The idea was that the form should comprise the clinical history of the case, particulars of treatment, and dietetic regime, the results of special examinations, and notes by the hospitals where the man had been detained.

Arising out of this, it was agreed, on the motion of General LANNE (France) and General ROUPPERT (Poland), supported by other delegations, that the secretary of the Permanent Committee of the Congress should be a liaison officer with the Red Cross Standardization Committee. Sir MATTHEW FELL said that some really practical results would follow this step.

Major DIEHL (Netherlands) and Dr. A. BAKESH (Hungary) supported a hearty vote of thanks to Sir Matthew Fell, President of the Congress, and Major A. D. Stirling, its indefatigable secretary.

VISITS AND EXHIBITIONS.

About 500 members visited the Halton camp of the Royal Air Force in Buckinghamshire. The R.A.F. hospital, the pathological laboratories, and the medical training centre were inspected, and afterwards there was an assembly at the aerodrome for a demonstration of the use of aircraft for carrying sick and injured, and the transfer of stretcher cases from aircraft to ground motor ambulances. The air ambulance was the subject of one of the discussions at the Congress, and also of a lecture by Major-General Bauer (Sweden).

The exhibition housed in the new extensions of the British Medical Association House was open throughout the week. One feature of special interest to both British and foreign delegates was the Daimler ambulance used to convey the King to Bognor. The body of this ambulance was designed and constructed by Messrs. Mann Egerton and Co. some four years ago, following suggestions made by the Medical Insurance Agency, who had been requested to ask their consulting engineers to design an ambulance which would give the greatest possible comfort and safety to the patient.

RECEPTIONS.

Two receptions were arranged for delegates on the evening of May 9th. A large party was given a warm welcome at a conversazione at the Royal Army Medical College at Millbank, where they were enabled to see how its many varied activities are carried on. They were received by the commandant of the College, Colonel H. E. M. Douglas, V.C. Another party was entertained at the Wellcome Historical Medical Museum, where the various exhibits excited great interest until a late hour. Dr. C. M. Wenyon, on behalf of Mr. H. S. Wellcome, who is abroad, expressed the pleasure felt at the opportunity of greeting representatives of military medicine from so many countries. Sir John Moore and Surgeon-Commander Bainbridge (U.S.A.) replied on behalf of the delegates.

On May 10th the official delegates were entertained to luncheon at Apothecaries' Hall, Blackfriars, by the Society of Apothecaries of London. The guests were received by the Master, Lieut.-Colonel C. Samman, and the deputy wardens, Dr. Bramley Taylor and Dr. Vincent Dickinson. After the King's health had been honoured the toast of "Our Guests" was proposed in a graceful speech by the Master, and very cordial responses were made by Commander Bainbridge of the United States Navy and Major-General Tobia of the Italian Army Medical Service. On the same day foreign dental surgeons were entertained to luncheon by the British Dental Association, and foreign pharmacists by the Pharmaceutical Society of Great Britain.

THE NEXT CONGRESS.

The next congress is to be held, on the invitation of the Hungarian authorities, at Budapest in 1931. The subjects for discussion will be the recruitment and training of military doctors and pharmacists; the psychoneuroses of war; methods of haemostasis on the battlefield; pharmaceutical questions; and the sequelae of war wounds affecting the teeth and maxillae.

The number of delegates and members attending the London Congress (without counting the ladies accompanying them) was approximately as follows:

France	107	Belgium	17
Poland	52	United States	13
Italy	45	Spain	12
Rumania	18	Czechoslovakia	9

Thirty other countries were represented by smaller numbers.

CONVALESCENT PROVISION IN THE UNITED STATES.

ESTABLISHING STANDARDS OF ADMINISTRATION.

IN a recent article in the *British Medical Journal* (February 23rd. p. 365) attention was directed to the fact that the provision of convalescent treatment, notwithstanding a general recognition of its importance, has received very little exact study in Great Britain. It is, for example, impossible to offer an adequate standard by which the extent of the convalescent provision required for any particular institution or area may be assessed, to provide criteria by which the efficiency of existing convalescent homes may be judged, or to describe with precision the machinery by which convalescent treatment is provided for those whose needs make it desirable. Information is so sparse and unco-ordinated that not only observers from abroad, but even those in intimate contact with our hospital administration, have been misled as to the extent to which convalescent treatment is actually available.

It is therefore interesting to note that in the United States the provision of convalescent treatment is in a somewhat similar position; in that country, however, the existence of the problem is more clearly recognized; and in the New York area in recent years attention has been given increasingly to the study of convalescence in its various aspects, and to the organization of a convalescent service. From the information available it seems that the existing convalescent provision in the United States is considerably less, relatively, than in Great Britain. In the article to which reference was made above it was shown that in Great Britain there are approximately 14,300 beds available in convalescent homes, while in twenty-two of the States of the United States there were available last year 12,812 beds. Of this number 5,685 beds were in institutions open in the summer only, 7,127 in institutions open throughout the year. The States included in this total comprise the most populous in the Union, the aggregate population being considerably more than that of Great Britain.

It is clear, therefore, that convalescent provision is more nearly adequate in Great Britain than in America, and to some extent this may account for the apparent indifference with which the matter is treated here. Convalescent facilities are very unevenly distributed in this country, but in the United States this feature is even more marked, and over one-half of the convalescent beds enumerated are in New York State and in New Jersey. In New York City, again, to a greater degree than in London, convalescent homes are independent institutions: in 1923, of 61 homes, only 7 were maintained and operated by hospitals. Most of the homes have been established by individual philanthropists, or by charitable organizations of one kind or another. As in Great Britain, a number of so-called convalescent homes exist largely to provide facilities for persons requiring restful holidays through minor ill health. In short, the provision of convalescent treatment in the United States presents no striking difference from that in this country, except in its extent.

There are, however, aspects of the problem about which the United States has much to teach. It has frequently been remarked that the American mind, more than the British, is concerned with the details of organization and the accumulation of information. American studies of convalescent provision certainly support this view. There is at least the beginning of an accumulation of literature on convalescence; an effort has been made in New York to assess the extent and nature of the provision required, and a centre for the collection and dissemination of information on convalescent facilities in the area has been established; furthermore, the Public Health Committee of the New York Academy of Medicine has prepared a pamphlet defining certain medical and administrative standards for the guidance of convalescent homes. It should be recognized, of course, that the movement described appears to be limited to the New York area; but it is probable that the interest generated by developments there will, before long, spread to other parts of the country.

The initiative in this forward movement was taken by the Public Health Committee of the New York Academy of Medicine, which, about five years ago, convened a conference on institutional convalescence and presented a report on convalescent care. As a result of this conference a convalescent service, governed by a representative committee and organized by a permanent secretary, was created in connexion with the information bureau of the United Hospital Fund of New York.

The first task of the service was to compile a directory of existing homes, giving the types of case admitted, the terms of admission, and other details, for each home. Its aim was to secure that the maximum use should be made of the facilities available. The need for such an organization is illustrated by the fact that in the New York area a recent investigation showed that only 72 per cent. of the capacity of the various convalescent institutions was utilized, while difficulty was being experienced in securing accommodation for convalescent patients—notably neurological cases, cases of nephritis and diabetes, cases requiring dressings, etc. Clearly a central clearing house can perform a useful function in securing a better adjustment between supply and demand; and what is true in New York in this connexion is probably also true in London and other centres of population in this country. It may be added that the directory of convalescent homes issued for the New York area is a model of what such a publication should be—telegraphically brief, complete as to detail, and authoritative.

The report on standards for the care and management of convalescent homes* consists of the reports of four subcommittees dealing with the convalescence respectively of medical, surgical, and neurological cases, and of children, together with a general summary by Mr. E. H. Lewinski-Corwin, and certain comments by Dr. Frederic Brush, who, as medical director of the Burke Foundation, has played a leading part in the development of convalescent treatment in the United States. The report treats of convalescence as "an important but neglected phase of medical interest," and emphasizes the need for the establishment of standards by which existing institutions may be judged. Reference is made to the value of "preventoria" for those on the verge of breakdown and other appropriate cases, but detailed consideration is restricted to provision for convalescence proper—that is, to provision for patients who have actually passed through acute illness, but are yet unfit to resume normal activities. It is suggested that neurological, cardiac, and orthopaedic patients, patients recovering from respiratory diseases or diseases requiring special diet, and children, should be segregated in separate institutions. A fifty- to sixty-bed unit is considered the optimum size, and that larger houses should consist of multiples of such units. Equipment should include a gymnasium and other physiotherapeutic and occupational requirements. The need for trained nursing and regular or resident medical attention is emphasized, and various suggestions are formulated for the maintenance of a close liaison between the hospital and the convalescent home.

Dr. Brush, in his comments, takes the view that "convalescence is the most important health segment now lacking organization and skilled direction," and formulates a suggestive programme to rectify this deficiency. His aim is to raise the status of convalescent treatment so that it may be recognized as an essential part of the machinery by which the health of the modern urban community is maintained. He considers that the convalescent service generally has fallen short of its task, and that its directors have failed fully to recognize their responsibilities. We in this country might well ponder his words in a self-critical spirit.

LITERATURE.

Institutional Convalescence: Standards for the Care and Management of Convalescent Homes. Report of the Public Health Committee of the New York Academy of Medicine.

Provision for the Care of Convalescents in New York City. By E. H. Lewinski-Corwin, Ph.D.

PREVENTION OF PLAGUE IN NORTHERN MANCHURIA.

THE sixth annual report of the North Manchurian Plague Prevention Service[1] covers the years 1927 and 1928, and is principally concerned with the pneumonic form. It embodies original observations which are the outcome of much research work on the problem of hibernation and perpetuation of plague among wild rodents, chiefly the tarabagan.

Pneumonic plague was probably the disease involved in the pandemic known as Justinian's plague in the sixth century. It played an important part in the Black Death (1346–52), where it was most prevalent at the *beginning* of many local outbreaks, passing in the later stages into the bubonic type. But, as in other branches of medicine, the facts recognized by only a few advanced thinkers were soon forgotten, and were not recalled until authors such as Hecker, Webb, and Husch in the nineteenth century defined its occurrence in modern Indian outbreaks and properly described the pneumonic features. It broke out occasionally in South-East Russia, but it was not till the investigations of Childe (Bombay) that the pneumonic form was definitely established as being a special entity of plague. Lung pest was never considered as more than an interesting but rare variety of plague until the great Manchurian epidemic of 1910–11 showed that it might assume dimensions comparable with those of the Black Death.

In Manchuria there were over 65,000 deaths in five months without a single known case of recovery, and the consequent clamour for more knowledge about this fatal disease caused the Imperial Chinese Government to convene an International Plague Conference at Mukden. The general belief among the delegates at that time was that this pneumonic epidemic form was due to the extremely cold climate causing human beings to huddle together indoors; man-to-man infection by breath droplets was thus made more easy, and *B. pestis* maintained high virulence by direct infection in the passage from lung to lung. In the present report, however, it is claimed that such an assumption was erroneous, since the disease also occurs during hot seasons and in countries with warm and even tropical climates. While this may be so, and people in hot climates live more in the open, pneumonic epidemics are limited to the overcrowded masses, and the disease only occurs very occasionally and sporadically among the richer classes, in much the same way as is the case with bubonic plague. The greater frequency is more apparent than real, far more attention being now paid to this deadly type than a few years back.

The rise of pneumonic plague outbreaks is attributed to the summation of different factors, such as the special character of the epizootics and susceptibility to lung diseases in general, or to plague infection. Extrinsic factors also indirectly contribute to the rise: climatic conditions may enhance the susceptibility of the lungs, while bad social conditions may impair the general resistance of the individual. But, in spite of all these, the difficult problem how this form of epidemic arises is by no means solved, though climatic and social conditions, together with the influence of measures taken, are no doubt instrumental factors in the spread and control of the outbreaks.

On the much-discussed point as to the tendency for these outbreaks to decline spontaneously, the report records investigations in the laboratories at Harbin and Vladivostock indicating that most of the cadavers dissected towards the end of the epidemic of 1920–21 did not show the usual pneumonic foci, but presented (though undoubtedly infected through the respiratory tract) only hyperaemic and oedematous changes in the lungs as well as marked general septicaemic features. These cases were designated *pulmonary* plague, and were much less infectious than those with the usual features of plague pneumonia, because in the former the disease runs the rapid course of acute septicaemia, and the principal medium of infection—the cough—is absent.

The findings as to the pathology of pneumonic plague hinged round the debatable question whether infection enters through the tonsils and reaches the lungs secondarily *through the blood and lymph stream*, or whether it is due to infection through the lower portion of the respiratory tract; all the work done by Drs. Wu Lien-Teh and Jettmar upon human cadavers, tarabagans, and sisels (small South Russian marmots) convinces them that the second view is the correct one. It is noted that infectivity is small during the first twenty-four hours after contact, but as soon as this stage is passed the patient becomes dangerous on account of a continuous increase of the cough and the number of bacilli emitted by it.

The value of vaccine prophylaxis has yet to be determined, and the same may be said of serotherapy. Also, there yet remains for study the possibility of the existence of a special ultra-virus or filter-passing form of *B. pestis* as the causative agent of pneumonic plague.

Much work is recorded on the perpetuation of plague among wild rodents, especially the tarabagan—the Siberian marmot. A considerable number of these animals, infected while hibernating, quickly succumbed to acute plague, and a peculiar form of latent plague was also found in which virulent bacilli survive either at the site of inoculation or in the regional lymph glands, or both. This appears to be the principal means of carrying over the disease from one season to another, and it may explain the mystery of the perpetuation of plague among hibernating animals. Dr. Wu deserves special credit for this important finding; the manner of perpetuation through the long Manchurian winter was a feature which greatly troubled the International Plague Conference.

A chapter in the report, dealing with recent knowledge of pneumonic plague, surveys researches in which the incidence, epidemiology, pathology, clinical features, and prophylaxis of the disease, as observed all over the world, are fully summarized. Though great progress has been noted, the riddle as to how pneumonic plague epidemics arise is evidently still unsolved. An extensive bibliography has been collated for reference. In an attempt to draw conclusions from the assembled evidence about plague in wild rodents the report says: "It must be emphasized that the more one learns about plague in wild rodents the more serious the problem appears. As a rule, once the infection has gained a foothold among such animals it not only perseveres, but even tends to spread whenever possible, sometimes at an alarming rate."

The report includes chapters by (1) Major G. A. Cullenden, M.D., on the morbid histology of pneumonic plague; (2) Dr. Lin Chia Swee on international aspects of pneumonic plague; (3) Dr. Li Yuan Po on a special kind of amoeba found in the faeces of tarabagans; (4) Dr. H. M. Jettmar on plague experiments upon insects; and (5) Dr. J. W. H. Chun, senior medical officer of the service, on plague investigations in a wide area of North Manchuria. There is an interesting chapter by Dr. Jettmar describing a year he spent in a Mongolian laboratory at Urga under the Russian Dr. Dudukaloff. He also writes on the vitality of scarlet fever streptococci. But the greater part of this report has been prepared by Dr. Wu Lien-Teh, formerly known as Dr. Gnoh Lean Tuck (South China orthography); he was a Cambridge research scholar and gold medallist in clinical medicine at St. Mary's Hospital, London. The North Manchurian Plague Prevention Service began its career under his direction in 1912, and has continued ever since to reflect the energizing activity and methods of research that he has instilled into it. There is an autobiographical chapter of his career. Taken as a whole, the volume may be regarded as a useful contribution to the subject of pneumonic plague, while it also shows that this Chinese prevention service has been brought into a good position among the modern European and American institutes of similar nature, and that China, by its help, is now beginning to take a more noticeable part towards the health betterment of the world. No fewer than seven hospitals are maintained by the North Manchurian Plague Prevention Service, which, in addition to many hundreds of in-patients, dealt with 69,770 out-patients between October, 1926, and August, 1928.

We are informed that this report may be obtained from the Cambridge University Press or from Messrs. H. K. Lewis, price 15s.

British Medical Journal.

SATURDAY, MAY 18TH, 1929.

NOISE AND ROAD TRAFFIC.

On October 23rd, 1928, the British Medical Association submitted to the Minister of Health a memorandum on noise and the public health. This memorandum (printed in the *Supplement* of November 10th, 1928, p. 209) represented not an isolated gesture of protest against the danger threatened to the mental and physical health of the community by the ever-increasing clamour on our roads and city streets; it was the culmination of a movement, begun by the Edinburgh Branch, which took definite shape at the Annual Meeting held at Cardiff in the previous July. On that occasion, after full discussion, the Representative Body unanimously adopted the following resolution: "(1) That in the interest of the public health the British Medical Association support any measures which may be taken so to alter or amend existing legislation as to give greater power to local authorities to suppress unnecessary noise which is disturbing to the lieges; and (2) that any noise from 11 p.m. to 6 a.m. which is capable of being prevented or mitigated, and which is dangerous or injurious to health, shall be a nuisance within the meaning of the Public Health Acts."

It cannot be held that the recently published proposals[1] made by the conference of local and police authorities and motor organizations, which was convened by the Minister of Transport to consider road traffic noises, are in complete accord with those set out in the British Medical Association's memorandum, but they go far towards being so. Their application would not subject us to the risk of living in an oppressive silence, but it would produce a welcome diminution in the volume of sound that threatens to engulf our civilization. The report of the conference, which is signed by Sir Henry Maybury, as chairman, draws a clear distinction between proposals whose effectiveness depends on the voluntary effort of motoring organizations, manufacturers, and the motoring public in general, and those which might reasonably be embodied in national legislation. In the latter class is the suggestion that a regulation should be made under the Motor Car Acts to deal with excessive and avoidable noises from motor vehicles which are badly constructed, badly loaded, or in a faulty condition. The conference proposes that under this regulation no person should use, or permit to be used, on the highway any motor car which, by reason of its construction or its load, creates any excessive noise; and it suggests that any noise should be regarded as excessive if it is caused, directly or indirectly, by faulty construction or condition, lack of repair or adjustment of the vehicle, or the faulty packing or adjustment of its load, and is in excess of that ordinarily created by motor cars of a similar class. The innocent driver is protected in the saving clause that it should be a good defence to proceedings taken under these regulations to prove that the noise in respect of which the proceedings have been taken was due to some temporary or accidental cause which could not have been prevented by the exercise of due diligence, or that it arose through the fault of some other person whose duty it was to keep the car in good condition or properly to adjust its load.

Probably the most perplexing problem before the conference was in relation to the control of the noise from horns and other warning instruments, and its proposed solution involves recommendations both for legislation and for voluntary effort. Horns of all types (electric buzzer, wind-blown, or electric motor driven) can be made with either objectionable or melodious notes, and the conference, unable to find any definition which would distinguish between different types of horns according to their notes, pleasant or otherwise, concluded that if any regulation were made the only course would be to permit the use of specific types which had been proved satisfactory by some kind of test as yet undetermined. Two causes of noise from motor horns have to be considered: the use of horns with an unduly strident note, and the excessive and unnecessary sounding of any kind of horn. With regard to the former the conference suggests that although a more powerful horn may be reasonable on the open road in rural areas, where in the daytime comparatively high speeds may be justifiable, in the hours of darkness the warning given by the headlights should reduce the need for a strident note to the minimum. Until the Ministry of Transport, in consultation with various scientific bodies and the motoring organizations and manufacturers, has succeeded in fixing a practical standard to which all horns should conform, the conference holds that much might be done if strong representations were made through the motoring organizations to the manufacturers and to the motoring public at large, drawing attention to the annoyance caused to the community by the use of strident horns, and urging them to confine the use of all types of horns to occasions when it is necessary in the interests of safety. The suggestion that zones of silence might be instituted where the sounding of motor horns would be forbidden, or permitted only on grounds of public safety, was uncompromisingly opposed by the motoring organizations, both on the ground that nothing should be done to interfere with the discretion of the driver in this matter, and that the enforcement of any such regulation would be fraught with considerable administrative difficulties. One must concede the argument of the motoring organizations that so long as failure to blow a horn is regarded by the police and insurance companies as an indication of responsibility for an accident, a certain amount of horn-blowing in self-protection is bound to occur. On the other hand, the conference recognizes that the use of horns when vehicles are stationary shows a lack of consideration for the public, and can be dealt with by regulations; it recommends that when a car is at rest on the highway no person should use or permit to be used in connexion therewith any instrument for the purpose of giving audible warning except on the ground of safety.

A most important series of recommendations concerns the reduction of traffic congestion—the chief cause of unnecessary horn-blowing in towns. Immediately applicable are the suggestions for the adequate name-plating of streets whereby the need of drivers to slow down their vehicles in an effort to discover their whereabouts may be reduced; for the adoption of a scheme on the lines of that recommended to the Minister of Transport by the County Councils Association, by which at road junctions traffic proceeding along a road of lesser traffic importance should be expected to look out for, and give way to, vehicles

[1] Report of Conference on Road Traffic Noises and Priority of Traffic at Cross Roads. H.M. Stationery Office. 1929. Price 2d. net.

proceeding along a road of greater traffic importance; and for the generous provision of signposts, especially at junctions which are known from accident statistics and otherwise to be particularly dangerous, above all where doubts may arise as to which is the road of greater importance. The needs of modern traffic can be met only by the most careful and far-seeing road planning. "The rolling English drunkard made the rolling English road"; and so long as there was no problem of traffic congestion the job could be left to him as well as to anybody else. To-day it has become important to plan roads and types of lay-out at road junctions not only with regard to present needs, but in anticipation of future needs. The conference, in considering these new problems, held that the lay-out at a crossing of two roads of equal traffic importance should be different from that of a crossing where a road of minor crosses one of major traffic importance; and from this point of view it suggests three classes of road crossings: (*a*) the crossing of two roads of major traffic importance; (*b*) the crossing of a road of major traffic importance by one of less traffic importance; (*c*) the crossing of a road of major traffic importance by a subsidiary road of quite minor importance. For each of these classes it is important to provide a lay-out which will induce drivers to act according to the traffic value of the road on which they are travelling, and for the first class a complete roundabout is suggested, for the second a partial roundabout, and for the third a "staggered" (that is, zigzag) crossing. The conference recommends further that when roads are being enlarged or new roads are under construction, sufficient land should be taken to enable a junction to be laid out in accordance with whichever may be the most appropriate of these systems, but that where it is not possible to lay out such a junction, illuminated beacons should be placed at the intersections of the roads.

The conference is to be congratulated on having produced an admirable report. While proposing a number of legislative changes, it has duly recognized that silence cannot be enforced by Act of Parliament, that there are aspects of the problem of noise which may best be solved by the public itself. Above all, its proposals for dealing with traffic congestion are informed with constructive vision, and their adoption will have effects far beyond the purpose of noise prevention for which they were designed.

THE REDUCTION OF MATERNAL MORBIDITY.

At a time when the subject of maternal mortality is given a prominent place in lay and professional discussions, when the whole country is crying out that it is as dangerous for a woman to have a child now as it was twenty years ago, and when promises to reduce the mortality rate are held out to the electorate as a party policy, there is a tendency to overlook any diminution that may have occurred in the amount of permanent disability left in the 99.5 per cent. of parturient women who do not die as the result of childbirth.

Dr. James Young, in an address on the woman damaged by child-bearing published in the *Journal* this week at page 891, presents what at first sight appears to be a depressing picture; yet it must be conceded that so far as the treatment of the late ill effects of child-bearing is concerned we have advanced very much in the last twenty years. The excellent results now obtained from plastic operations for prolapse afford a good example of the improvements that have accrued from the experience of the last generation of gynaecologists; and, since pelvic surgery has become a reasonably safe procedure, many women who a generation ago would have become permanent invalids can now be restored to health and useful activity. These, however, are improvements in gynaecology, not in midwifery. Although it is impossible to assess the amount of damage that occurs as the result of child-bearing, it has been shown that well over half of the gynaecological beds in the hospitals of this country are filled with the after-effects of complications of labour. But when we consider the relative rarity nowadays of such gross injuries as urinary fistula we must conclude that the practice of midwifery has improved in recent years. That the gynaecological beds are still full is due merely to the fact that gynaecologists now operate for lesions that formerly were not regarded as severe enough to warrant operation.

Since the scope of operative intervention in midwifery has been widened there can be little doubt that the amount of immediate suffering during labour has been decreased. Although it may be possible that infections and lacerations are in part due to operative procedures, the corresponding lessening of psychological trauma must not be lost sight of entirely when comparing the results of to-day with those of years ago. The substitution of Cæsarean section for a labour lasting several days and perhaps ending in craniotomy, the shortening of the second stage of labour by a low forceps operation, and the alleviation of labour pains by means of sedatives and anæsthetics—all these measures must not be condemned because they have not resulted in a diminution in the death rate among the 0.5 per cent. of women who die in consequence of childbirth. They may have saved a number of the remaining 99.5 per cent. from an ordeal of suffering so great as to leave its mark on the patient for the rest of her life.

In every branch of medicine we demand more perfect results with the advance of the art; in midwifery in particular, in our anxiety to reduce the mortality rate, we must not lose sight of those women who suffer permanent damage which may cause lifelong disability. There is in this direction still much room for improvement, but when present-day results are compared with those of former years, we have at least some grounds for encouragement in the progress already attained.

VENOUS BLOOD PRESSURE.

DISTENDED cervical veins and an engorged liver constitute the simplest demonstration that in cardiac failure there is increased pressure in the great veins and right auricle. Investigations of the venous pressure in health and disease therefore hold, besides an academic interest, the possibility that incipient failure may be demonstrated by exact methods for the measurement of this pressure. The direct method by vein puncture and manometry was introduced eighteen years ago by Moritz and Tabora,[1] and since then the mechanisms controlling the venous return to the heart and the transit of blood from the capillaries to the great veins, have claimed increasing attention. It is clear that a large number of factors must be in operation: the force of the heart, the tone of the arterioles, the great fluctuations demonstrated by Krogh in the capillary bed, and the rate of the heart are but a few of them. Further, it is obvious that venous engorgement may arise either from inadequacy of the heart in transferring blood into the

[1] *Arch. f. Klin. Med.*, 1910

systemic circulation or from altered peripheral conditions facilitating passage of blood from the arterial to the venous system. This principle explains the seeming paradox that individuals with prominent veins in the extremities may have no reduction of effort tolerance, while the subjects of cardiac failure often show no peripheral venous distension. The normal venous pressure as measured in the basilic vein, with the patient and the arm in the horizontal position, is generally held to be between 5 and 15 cm. of water. Readings within these limits were observed in 90 per cent. of normal students by Bedford and Wright[1]; these observers further found, in agreement with other workers, an increased pressure in the veins in cardiac failure. A comprehensive survey of venous pressure in its relation to heart disease has recently been made by Harris,[2] who confirms the relation of increased tension to failure, with the exception of certain cases in which the arterial pressure is high and the pulse slow. The pulse rate is regarded by this author as controlling to a large extent the venous pressure; observations made on patients suffering from hypertension and compensated heart disease showed generally normal readings, while if the pressure in the veins was increased there was a tendency to rapid pulse rate. Likewise in those conditions typically associated with rapid rhythm, such as auricular fibrillation, exophthalmic goitre, paroxysmal tachycardia, and effort syndrome, high venous pressures were found. In his discussion of these results Harris attributes venous engorgement to a primarily increased pulse frequency which entails reduced output per beat, and, since the augmented rate does not compensate for reduced efficiency of the beat, a reduced output per minute. He thus inverts the mechanism described by Bainbridge, in which auricular distension reflexly evoked increased heart rate. This matter, however, seems still open to question. With a good venous return the filling of the heart is almost complete before the conclusion of diastole, so that the initial result of increased rate is greater output; conversely, if the venous return is poor, diminished output results from acceleration of the heart. Harris's argument thus postulates inadequate venous filling, but, whatever may be the explanation, a relation between high venous pressure and rapid rhythm has been established by this work. In its special relation to arterial hypertension the venous blood pressure has been investigated by C. Alexandresco-Dersca[3] and his collaborators. In the presence of right heart failure or renal disease, measurements between 17 and 60 cm. of water were found; high readings were also recorded where intrapulmonary tension was increased. Patients with uncomplicated hypertension showed normal venous pressures, but the latter were reduced in the presence of arteriosclerosis or other lesion involving the small arteries and capillaries. Whether or not estimations of pressure in the veins may assume more than a physiological importance remains to be seen. There is no doubt that the method has provided an additional means of attacking the many problems still to be solved concerning the mechanics of the circulation. As a diagnostic aid in cardiac failure the measurement of venous pressure appears, from the results obtained by Bedford and Wright, to be of limited value, increase in the pressure being always accompanied by other signs of failure. There remain, however, the provinces of prognosis and therapeutics. It may well be found, in the light of future knowledge, that venous pressure measurements are of value in estimating improvement or deterioration in a patient's condition. Possibly also they may be of use in determining which of the therapeutic measures employed in hypertension and in cardiac failure are of greatest benefit.

PRINT AND READING.

THERE has been issued under the aegis of the Committee upon the Physiology of Vision of the Medical Research Council the report of an interesting piece of research work by Mr. Vernon, of the Psychological Laboratory of Cambridge University, on "Errors made in reading."[1] In experimental work upon the legibility of printing type it has been assumed that confusion between letters will occur as much in reading connected meaningful material as in reading single letters, nonsense words, and disconnected words. On this account some have clamoured for the alteration of the shapes of various letters which, by experiments or *a priori* reasoning, were held to be ambiguous and easily confused with other letters. Others found that words were not perceived letter by letter, but from a few "determining" or "dominant" letters, of which the initial letter and the letters extending above and below the line are the most important; or from the total word-form; or from a combination of these two factors. Others, again, found that some people read more by word-wholes, some by "dominant" letters. Thus it seems that confusion between individual letters is unimportant in connected reading, unless they are dominant letters. Experiments were therefore undertaken to determine how far typographical errors, and especially the mutual substitution of readily confused letters, affected the legibility of various kinds of reading matter. Various types of test material were used, from disconnected words to meaningful passages: the print was exposed for brief periods in a specially lighted tachistoscope. Students and research workers in psychology were subjected to the tests, and the type of error made by them in reading these tests was investigated. Subjects were instructed to read aloud as rapidly as possible all that they saw, and to report guesses as to words or parts of words of which they were not certain. The mistakes showed, speaking generally, that alteration of the total word-form was quite as common as substitution of letters with preservation of the total word-form. Shortening of the word-form was more common than lengthening. There was no evidence that one particular part of the word rather than another "determines" how the word shall be read; but there was evidence that the vertical "elevation" of the words was more correctly apperceived than their horizontal extension, and that the general contour of words, as indicated by the relative heights of the letters, was of considerable importance in reading them. Letters found to be most frequently replaced fell into two groups, ascenders and small letters. Of ascenders, *f* and *t*, and *l* and *t*, were the most confused: *d* and *l*, *d* and *t*, and *h* and *t* were also substituted for each other. Among the vowels, *o* and *e* gave difficulty; there was a natural tendency to introduce *e*, the most frequently occurring letter of the alphabet. It is unfortunate that *a*, *e*, and *o* are all small curved letters resembling each other closely; but it was noted that *e* and *i*, which are not alike, were almost as commonly confused. Thus, the view that typographical resemblance is the preponderating factor leading to the frequent mutual substitution of the vowels was held to be incorrect. There would appear to be some call for the alteration of the form of *a*, *r*, and *s*, and for the differentiation of *f* and *t*, though the subjects of the experiment occasionally made mistakes from other causes; they would read into a line a word from the line above or below, and made further errors by failing to begin on the succeeding line. Mr. Vernon's general conclusion is that when the meaning of the material read is fully comprehended, typographical errors, being few in tachistoscopic reading, would be negligible in normal reading. When the meaning is not understood, or when there is no continuous context, unfamiliar words

[1] Privy Council. Medical Research Council. Reports of the Committee upon the Physiology of Vision. Studies in the Psychology of Reading. London: H.M. Stationery Office. 1929. Pp. 59. Price 2s. net.

or long and difficult words are replaced by familiar words of a somewhat similar form and appearance, or by much shortened words or nonsense combinations. Thus, mutual confusion of individual letters is only a minor cause of errors in reading.

DANGEROUS DRUGS AND THE FAR EAST.

ARISING out of the Geneva Opium Conferences of 1924–25, a commission has been set up by the League of Nations to inquire into opium smoking in the Far East. The contributions of the French, British, and Netherlands Governments to the expenses of the inquiry have been increased, and the League's Council now regards the financial position as sufficiently assured. M. Ekstrand, the Swedish Minister at Buenos Aires, has been appointed chairman of the commission, and he has as his colleagues M. Max Leo Gérard, honorary secretary to the King of the Belgians, and Dr. Jean Havlasa, the Czechoslovakian Minister at Rio de Janeiro. It will be remembered that The Hague Opium Convention of 1912 pledged the contracting Powers to bring about the gradual and effective suppression of the manufacture of smoking or prepared opium, and to prohibit its import and export either immediately or as soon as possible. The Geneva conference relaxed these requirements to the extent of postponing the suppression of smoking opium until not more than fifteen years from a date when the commission, now appointed, shall have decided that the export of the drug from producing countries no longer constituted an obstacle to the reduction of opium smoking in consuming countries. China was no party to this engagement, although exports, whether licit or illicit, from that country were regarded as the chief obstacle to the contemplated suppression. At the twelfth sitting of the Opium Advisory Committee the representative of China made a lengthy statement on the whole question of the attitude of China to opium smoking and to the illicit traffic in opium, morphine, and cocaine generally. This statement, which contained many historical and political references of a polemical character, was refused discussion by the committee, and has now been published by the "Ligue anti-opium d'outre mer." Mr. Wang King Ky therein urged that the commission which has just been appointed should have its inquiry extended "to cover all opium-producing countries or countries manufacturing its derivatives," with a view to securing conformity with Article 9 of The Hague Convention, and restrict the manufacture, sale, and use of dangerous drugs to medical and scientific purposes. He quoted Mr. Porter, the United States representative, who said: "There must be only one standard of morality for the world, not one for the West and another for the East. What is forbidden and punished with severity in the West must not be excused and defended and promoted in the East." It is no longer possible to deny that tons of morphine, heroin, and cocaine manufactured in European countries have been finding their way to the Far East, and, as Mr. Sato, the Japanese delegate, observed, there is no reason why "the flood of morphine and heroin into China should not be considered at the same

party policy, the

tuberculous patients. The number of deaths from pulmonary tuberculosis was too small to form a basis for any conclusion, but in the case of non-pulmonary tuberculosis, in which two-thirds of the mortality was due to tuberculous meningitis, the death rate was significantly greater among children living in tuberculous households than the corresponding rate in the geographical county of Lancashire, used as a "control." In cases where the adults in the households had positive sputum the excess mortality from non-pulmonary tuberculosis amongst the children was from nine to nineteen times greater, according to the age group, than among the controls. Where the sputum of adults was negative or absent, the non-pulmonary tuberculosis death rate of children was also greater than that in the county rate, but not sufficiently so to be statistically significant. The mortality was higher among children of mothers with positive sputum than of fathers. When the death rate from all causes of the 1,486 children was examined, it was found that during the first year of life the rate for the children in tuberculous households was significantly below the corresponding rate for Lancashire. Between the ages of 1 and 2 years the rates were about the same, while in the age group 2–5 years the death rate from all causes in the children of tuberculous households was significantly higher. This curious observation in children under 1 year old has perhaps some interest in connexion with Professor Calmette's assertion that infants vaccinated with B.C.G. show a greatly diminished death rate from all causes as compared with the general death rate. Dr. Lissant Cox seems inclined to attribute the difference to extra supervision by the medical and nursing staffs in the case of tuberculous households, and to the consequent advice in feeding and health, and the assistance given to necessitous cases. In connexion with this lowered mortality from all causes in children under the age of 1 year, Dr. C. W. Laird, one of the group of officers engaged in the investigation, recalls the claim of Professor Abderhalden of Halle to have discovered proteolytic ferments in the blood of pregnant women which were not to be found apart from pregnancy. Further reference to Professor Calmette's work is made in the report in stating the actual death rate from tuberculosis in Lancashire. Whereas Professor Calmette calculated that in France 24 per cent. of the children of tuberculous mothers died from tuberculosis in the first year of life, the corresponding figure for Lancashire was only 3.2 per cent. The death rate from all causes among these children was only 11.5 per cent. Further, the Lancashire investigation of children observed from birth to the age of 4 revealed a mortality figure, both from tuberculosis and from all causes, which was a little lower than the French figure for corresponding children vaccinated with B.C.G., and much lower than that for untreated French children.

ROENTGENOLOGY.

Roentgenology[1] is the title of an essay, in book form, by Dr. G. W. C. Kaye, superintendent of the Physics Department of the National Physical Laboratory. It makes very interesting reading. The book divides itself into three main parts, of which no doubt the first and the last will prove of most interest to the ordinary reader. Dealing with the first part, we find that this is a fascinating account, the matter being arranged in chronological order, of the evolution of electricity and its bearing on the discovery of *x* rays. It relates shortly the discovery of essential features, and gives the name of the discoverer and the date of the discovery. This part is beautifully illustrated by numerous portraits, drawings of original apparatus, photographs of Wilhelm Konrad Roentgen and of

[1] *Roentgenology.* By G. W. C. Kaye, O.B.E., D.Sc. London: W. Heinemann (Medical Books) Ltd. 1928. (Cr. 8vo, pp. xiv + 157; 43 figs., 1 plate. 7s. 6d. net.)

laboratory, and a reproduction of the first *x*-ray photograph of the human hand made in England. The second part deals successively with the nature of *x* rays; reflection, prismatic refraction, diffraction of *x* rays, and the nature of radiation. This part will interest physicists and some radiologists, but is too technical for the majority of medical men. The concluding part deals entirely with the dangers of *x* rays, protection for workers, and the recommendations drawn up by the British X-Ray and Radium Protection Committee and those adopted at the second International Congress of Radiology in 1928. The author describes the evolution of protection, and the reasons for the various recommendations, and he also discusses in detail the protective value of various metals and other materials. Over one hundred persons lost their lives, and many more were injured, before *x*-ray work was made safe. Thanks in a very great measure to Dr. Kaye's own work, there is no reason now why any further loss of life or health should occur.

EDUCATION AND THE PREVENTION OF MALARIA.

THERE is an inclination both among those holding official appointments in health departments and among the populations whom they serve to think that healthy conditions of living can, and should be, created by official action. The private individual, though ready enough to admit the failure of officialdom to create healthy conditions, is disposed to blame "Government inefficiency" rather than the inherent weakness of the system. Experience may be relied upon to teach the health official that the essence of the problem is the education of the individual in fundamental matters which affect his health. The problem is familiar at home, but it is much more pressing in those foreign parts where a more primitive social and sanitary organization coincides with more numerous and more varied, but none the less avoidable, disease risks. Particular interest therefore attaches to a new move announced from Kenya, where the medical department has adopted the slogan "Every man his own health officer," and where the word "propaganda" has appeared in the Colony's estimates. Far from relying on the inherent blessedness of the word, the medical department has made arrangements for what appears to be an effective scheme, admirably suited to the Colony's needs. There has been created the appointment of "special farm medical officer," first among whose duties comes "continuous safari on the farms, personal propaganda with regard to how to avoid malaria and how to make the farm healthy." He will travel from one isolated farm to another, camping at each for sufficient time to get to know the farmer and his difficulties, to examine thoroughly the labourers, and to teach practically and on the spot the feasible remedies for unsatisfactory conditions. Even in Great Britain much might come of some such scheme, but two factors make it especially valuable in the tropics, where the problems of no two homesteads are identical. Taking malaria alone, the preventive measures desirable and practicable at one farm may differ widely from those at another ten miles away. Moreover, such sanitary measures as are to be applied—for example, in regard to the water supply and the disposal of excreta—may often, of necessity, have an element of makeshift, or at least require expertly directed ingenuity. How many health officers in the tropics have said to themselves: "If only I could sit down beside this fellow for a week I could really do something"! When the Kenya scheme was mentioned at the Royal Society of Medicine the other evening, a distinguished administrator from another African territory said that in his domain medical officers had been visiting farms for many years, and he was pleased to hear that Kenya was now going to do the same. But the casual visit of a district medical officer, whose duties at his headquarters are meanwhile accumulating, is a very different thing from that now instituted in Kenya. It seems probable, for example, that the Kenya plan would go a long way to control the blackwater fever which has been such a bane to white colonists in Southern Rhodesia.

A MODIFIED FORM OF THE WASSERMANN TEST.

THE Medical Research Council has issued a report[1] on the technical details of the Wassermann test (No. 1, M.R.C.) as modified by Dr. E. J. Wyler. When the Medical Research Committee (as it was then named) published in 1918 two reports relating to the technique of four variations of the Wassermann test, Nos. 1 and 3 appeared to be of equal value as regards sensitivity and accuracy. For many years Dr. Wyler has been using the well-known No. 1 method, with certain modifications introduced by himself, and the present report gives full details of his technique. The precautions taken include securing that the temperature of the water in the inactivating bath is uniform throughout; standardization of the sheep-cell suspension by the Haldane haemoglobinometer; the employment of pooled guinea-pig serums from selected animals for complement; and the use of a dropping pipette. Dr. Wyler emphasizes the importance of adhering rigidly to the same exact "ritual" from day to day. The hope is expressed in the report that with the aid of this information other workers will be able to conduct the investigation so as to obtain strictly comparable results.

THE next session of the General Medical Council will commence on Tuesday, May 28th. The President, Sir Donald MacAlister, Bt., K.C.B., M.D., will take the chair at 2 p.m. and give an address.

IN accordance with the statutes of the College, the Fellows of Trinity Hall, Cambridge, have pre-elected Professor H. R. Dean, M.D., to succeed Dr. Henry Bond as Master on June 17th next. The Master-Elect has been a Fellow of Trinity Hall since his appointment as professor of pathology in the University in 1922.

WE much regret to have to record the death of Mr. Arthur Henry Cheatle, C.B.E., F.R.C.S., who was for many years aural surgeon to King's College Hospital, and presided over the Section of Otology at the International Congress of Medicine in London in 1913. We hope to publish an obituary notice in an early issue.

A BRONZE portrait bust of the late Sir Clifford Allbutt, Regius Professor of Physic from 1892 to 1925, will be unveiled by Sir James Crichton-Browne, in the Allbutt Library at the Medical School, Cambridge, to-day (Saturday, May 18th), at 2.30 p.m. Lady Allbutt, the donor of the portrait, will be present, and invitations to the ceremony have been sent to a few friends. The Allbutt Library occupies the room formerly known as the Kanthack Library, which has been removed to the new Pathological Department.

[1] Privy Council: Medical Research Council, Special Report Series, No. 129: The Wassermann Test. Technical Details of No. 1 Method M.R.C. (modified). By E. J. Wyler. H.M. Stationery Office. 1929. Price 9d. net.

THE Hanbury medal of the Pharmaceutical Society of Great Britain "for high excellence in the prosecution or promotion of original research in the natural history and chemistry of drugs" has been awarded to Henry Hurd Rusby, M.D., professor of materia medica in the College of Pharmacy of the Columbia University, New York, and director of the New York Botanical Gardens. It is hoped that Professor Rusby will visit England next autumn to receive the medal.

CANCER OF THE COLON.

ANNUAL ORATION OF THE MEDICAL SOCIETY OF LONDON.

THE annual oration of the Medical Society of London was delivered on May 13th by Professor G. GREY TURNER of Newcastle-on-Tyne, whose subject was "Cancer of the colon." Dr. J. WALTER CARR, president of the society, was in the chair.

Professor GREY TURNER, who held his hearers' attention for a full hour and a half, and spoke entirely to lantern slides, began by giving some personal statistics. He said that he had had the opportunity of operating on 241 cases of cancer of the colon. Out of that number he had been able to do some type of resection of the growth in 142; only a palliative operation was possible in 85, and in 14 only an exploratory laparotomy. He was not able to furnish the number of cases brought to his notice out of which these cases for operation had been selected, but his operability rate had been extremely high. It was clearly understood that in operating for cancer the ideal was to excise the whole of the diseased part, together with a wide area of healthy tissue, which latter should include the path of probable cancer invasion. This was probably as well illustrated in connexion with growths at the ileo-caecal angle or in the caecum as in any part of the body.

The results of the 142 cases in which resection was done showed 27 deaths; in 58 of these cases, with 15 deaths, the operation was done before the end of 1919, and in 84 cases, with 12 deaths, it was subsequent to that year. In the former period the mortality was nearly 26 per cent., in the latter period 14 per cent., but he added that he was by no means satisfied with this last figure. His aim was to reduce the mortality to 5 per cent., which would, however, mean the acme of judgement and technical skill. As to the parts of the bowel involved, one constantly read in surgical publications that malignant disease was different according to the part of the colon in which it appeared, the difference relating to clinical history, symptoms, and prognosis after operation, so as considerably to affect the ultimate results; but in his own comparatively small series of cases he had not found this to be so. The great majority of the growths had been in the sigmoid (69 out of the total of 142); the caecum was involved in 22, the ascending colon in 6, the hepatic flexure in 7, the transverse colon in 14, the splenic flexure in 15, and the descending colon alone in 9. The most frequent of his cases was that in which the descending colon was involved right down to the bottom of the sigmoid.

Mortality.

It was a salutary thing for a surgeon to ponder over his deaths. Professor Turner showed a table in which the causes of the 27 deaths were set out. In 15 cases the death was due to peritonitis or other sepsis; in 3 to intestinal obstruction; in 3 to pneumonia, and single cases to haemorrhage, shock, diarrhoea, heart failure, exhaustion, and unknown cause. With regard to the deaths from peritonitis or other sepsis, in a good many of the cases there had not been general septic peritonitis, but some form of sepsis, sometimes in connexion with the glands, and sometimes in connexion with the peritoneal cavity generally. The element of obstruction had a good deal to do with the ultimate mortality. The other deaths which had occurred in this series, apart from the large group associated with sepsis, were just the sort of deaths that had to be recorded from time to time in intra-abdominal surgery of any sort.

Tennyson's line, "Knowledge comes, but wisdom lingers," was very appropriate here. If wisdom were parallel with knowledge he would not have lost his last two cases. In one of these, on a very stout person, he carried out an anastomosis at one stage; in the other he essayed a one-stage operation in a weakly, frightened old man. The two-stage operation might have carried them through. Of this series of 142 cases, 70 operations were done in one stage, and 72 in two or more stages. In all, 267 operations were required. What was called the two-stage operation (though in fact the operations were usually more than two) showed only half the mortality of the one-stage operation—12.5 per cent., as against 25.71 per cent.—which was a very striking and informative figure.

Grade of Malignancy.

Instead of looking on obstruction, as so many people did, as an undesirable thing from the patient's point of view, he was inclined to think it most favourable. If a patient developed an obstruction in the early stage of malignant growth, thus demanding an operation for drainage, that patient was more likely to get well after a subsequent radical operation for removal of the growth. The obstruction drew attention to the condition at a stage at which the malignant disease was probably in an operable state.

Just as many surgeons thought that obstruction in these growths was a very bad thing, many had assumed that malignant disease in the large bowel was of low grade; but there was no doubt that these growths varied greatly in malignancy. He himself was not able as yet to say while the growth was *in situ*—which was the only useful time—what was the degree of malignancy of the growth. He showed a specimen of a constricting carcinoma of the sigmoid adherent to the appendages which he had removed from a very fat woman, who lived fourteen years and ten months after the operation, while in an exactly similar case the patient died in less than two years from a recurrence of the growth.

It was quite likely that a great many cases of carcinoma of the colon never reached the surgeon. The surgeon was never asked to see them. Many of them masqueraded under the care of physicians as cases of ascites or secondary carcinoma of the liver. But he did not think it fair to assume that all bowel growths were of a low grade of malignancy, though there could be no doubt that many of them did exhibit such low degree. He was accustomed to say to his students that whatever some surgeons might believe with regard to carcinoma, however much they might believe that carcinoma was a generalized disease and never had a purely local origin, that was the worst possible attitude of mind for the operating surgeon. If the surgeon was to do good to his patient and to subject him to a sufficiently radical operation, it was extremely important that he should have faith at the time he did the operation that he was dealing with a local disease.

Operability.

This brought him to the question of operability. He felt that at the present time, when radium was reaching such a wonderful field of usefulness, and was being employed tentatively in the treatment of malignant disease of the internal organs, it was very important to decide what operative measures could offer for patients suffering from such disease. He had little confidence in surgeons who, while they presented excellent statistics as to their after-results, rejected an undue number of cases, selecting only a comparative few for their surgical enterprise. He had more confidence in the man who, although he might have a big mortality, had also a big operability rate.

First of all, one must not be deterred by the age of the patient. He instanced a woman of over 70, with carcinoma of the ascending colon, who had done extremely well; recently he had had under his care a man of 86 with carcinoma of the descending colon, and he had made an equally satisfactory recovery. Nor need the surgeon be deterred by the mere size of the growth, nor by the local spread, whatever the parts to which it was attached. The more important question was that of distant dissemination; in the selection of these cases it was the surgeon's duty to make a thorough search for such dissemination. It was only the cases with distant dissemination that need be absolutely rejected so far as operation was concerned. He had made it a working rule that if in the presence of malignant growth there was no unequivocal sign of distant dissemination it was the surgeon's duty to offer that patient the chance of operation. There was, however, a type of spread of these growths which was undoubtedly unfavourable—namely, extensions towards the mesentery. Extension away from the mesentery was of little moment.

The best comment he could make on the question of operability was to invite the attention of his audience to

some of the cases in which he had been able to carry out multiple resections. In one case he had opened the abdomen in a man who was clearly suffering from a large malignant growth about the splenic flexure. There was no distant dissemination, and therefore, following the rule of which he had spoken, he explored the abdomen and found the growth involving the small intestine and the stomach. He made an anastomosis between the ascending colon and the sigmoid, and within a fortnight this patient, having been relieved of his obstructive symptoms, was well enough to undergo the radical operation, and was now alive and well nearly three years afterwards. It was better to do rather too much than too little, especially if, as in many of these cases, it really did not add very considerably to the risk of the operation.

Restoration of Continuity.

In any operative procedure the patient, perhaps unfortunately, only estimated the advantage of surgery by the perfection of the functional result. The patient had no nice appreciation of the technical difficulties. Therefore one attempted to make a perfect job by restoring the continuity of the bowel. Out of the 142 cases in which the growth was excised he had done excision with restoration of continuity in 124. Included in this group were 8 cases operated upon by Paul's method; incidentally Professor Turner said that he thought the work of Paul of Liverpool had been of very great value in the evolution of intestinal surgery. It would stand out as one of the milestones on the long road of surgical progress. Nevertheless, Paul's method was one that he was not in the habit of using if he could help it, because it took up a large amount of the intestine. In the 8 cases so operated on there were 2 deaths. In the whole group of 124 cases there were 24 deaths. In the remaining 18 cases out of his 142 the procedure was excision with permanent colotomy; there were 3 deaths.

After-History of Survivors.

What of the after-history of the patients who survived the operation? Out of 115 who survived, 32 were either alive or were known to have died without recurrence more than five years after operation; 31 were known to be alive and well without recurrence less than five years after operation; 2 died within a year without recurrence; 41 were known to have died of recurrence; 3 were alive, but with recurrence, and 6 had not been traced. In explaining the large proportion of cases which it had been possible to trace, Professor Turner said in an aside that he had hit upon an effective method of tracing patients. Instead of marking the envelope "If undelivered return to ——," he had left it unmarked, and, the letter being delivered at the house, female curiosity prevailed, and in many cases he got information from the present occupier as to the whereabouts of the patient. Of the 26 patients who were alive and well more than five years after operation, 2 had survived for more than fifteen years, 7 others for more than ten years, and 9 more for longer than seven years. Of the 31 who were known to be alive and well less than five years after operation, 10 had survived for over three years, and 8 for over two years. The tendency to recurrence certainly diminished after five years. He liked to stick to the five-year period, though he noted in some recent publications that surgeons were still talking of the three-year period. His own figures for the two periods were as follows: out of 82 cases operated upon more than five years ago and who survived the operation, 32 (39 per cent.) were alive without recurrence or were known to have died of other causes; of 97 cases for the three-year period, 42 (43.3 per cent.) fell in with the condition as stated. Of the 41 patients known to have died with recurrence, 1 lived over seven years, 8 lived between three and seven years, and 18 between one and three years; in 14 cases there was recurrence and death within less than twelve months. The great majority were perfectly well until the symptoms of recurrence appeared, when they died quickly.

Palliative Operations.

The palliative operations, he was afraid, presented a sorry picture. They were the bad residue. The short-circuiting operation had been done in 45 cases, with 9 deaths; 7 of these cases had not been traced, and 29 were known to be dead, their average duration of life being just under eight months. Some type of colostomy was done in 40 cases, with 15 deaths; 5 of the cases which survived operation had not been traced, 4 were alive, and 16 dead, the average duration being again eight months. In the 14 cases in which explorations only were done there were 6 deaths. In spite of this unhappy record, he thought one need not deny the possible benefits of operation to any patient if that operation was going to relieve obstruction and pain.

Methods of Examination and Operative Technique.

Turning to diagnosis, Professor Turner said that the classical symptoms which one read about in some textbooks were the symptoms in the late stages of the disease. The conditions which it was most important to note were recurring attacks of colic, with complete relief, or not, in between. He attached great importance to consideration of haemorrhages from the bowel in persons past middle life when there was no local explanation. In the great majority of cases the bowel growths could be ascertained by abdominal, rectal, and bimanual examination, repeated under varying conditions, by observation of stools, the use of the sigmoidoscope, and the barium *x*-ray enema. The consulting surgeon had the poorest opportunity of making a diagnosis; it was the man who had the patient under frequent observation who was better able to assess the condition. The patient might show no physical signs at one time, and at another the signs might be perfectly obvious. While appreciating the sigmoidoscope, a warning was necessary. He had seen the sigmoid perforated by the use of this instrument, and he had learned of four such cases from his colleagues. With regard to *x*-ray examination, this had a definite meaning and importance in a gathering of experts, but one had to remember that these patients were scattered over the country under the care of those who had little experience of the *x*-ray method, and there it was by no means the absolutely certain thing that some people thought.

In the case of big distended abdomens he favoured a blind caecostomy, though caecostomy had its limitations, and sometimes it would be better if a preliminary colostomy were made. In the actual conduct of the resection operation he wanted to draw attention to the extreme importance of proper mobilization of the growth. In his time there had been nothing more valuable in connexion with the surgery of the large bowel than, first, the recognition of the necessity of preliminary drainage in cases of obstruction, and, secondly, the appreciation of the importance of thorough mobilization under the guidance of the eye. In the absence of distant dissemination there were very few growths which would not lend themselves to local removal if the mobilization was properly carried out. With the aid of many illustrations, Professor Grey Turner described the classical operations, mentioning that operations in the theatre were rather different from those depicted in the textbooks, and that it was extremely difficult to make good textbook illustrations. Because it was not always possible to carry out classical resections, he was afraid that many people were deterred from doing a radical operation. The modern surgeon must be catholic in his methods, must know exactly what he wanted to do, must have properly planned incisions—here the orator paid a grateful tribute to his master, Professor Rutherford Morison, especially for his teaching with regard to an ample muscle-cutting incision—and must have certain principles before him. A standardized operation was not possible. Standardization in operations would only be possible if patients were standardized, and pathology also. But in intestinal resection it was most important to follow certain general principles, also to see absolutely clearly the parts to be dealt with, and, above all else, to assure the vascular supply. The orator concluded with a quotation from Gladstone: "Let us cherish a sober mind, and take for granted that in our best performance there are latent many errors which in their own time will come to light."

A warmly accorded vote of thanks was proposed by Mr. H. W. CARSON and Mr. A. J. WALTON, and Professor GREY TURNER, in reply, suggested that the society, by means of

a scholarship or lectureship, might do something to help the older men in practice who had come to the end of their hospital appointments, so that they might be encouraged to devote some of their time to working up their cases.

ANNUAL MEETING OF THE SOCIETY.

At the annual meeting of the society, which preceded the oration, Mr. Donald J. Armour was elected president for the session commencing October, 1929. It was reported that the number of Fellows stood at 627.

Nova et Vetera.

THE MAP OF ROMAN BRITAIN.

ARCHAEOLOGY has always been a favourite study with medical men, many of whom have been notable contributors to the science. An inductive science, based on facts none too easy to ascertain and demanding common sense and a wide range of ancillary sciences for their interpretation, is naturally attractive to minds trained in observation and reasoning by clinical medicine.

The new edition of the Ordnance Survey "Map of Roman Britain" may be looked upon as the latest chart exhibiting the archaeological facts so far observed of one of the most interesting periods of our history; and an attempt to base a picture of the Roman occupation upon them cannot be without interest.

It is true that written record is not wholly wanting, and a summary of events is duly noted on the chart, but the historical material is notoriously meagre. The Claudian conquest in A.D. 43, Boudicca's rebellion, the Conquest of Wales in 78, about five successful incursions from Scotland, at intervals of twenty-five or thirty years as each new generation grew up, one long period of sixty-five years' peace and prosperity in the third century, before the Saxon raids began, a few usurpations and civil wars among the Romans, the invasions of the West of Scotland and England in the fourth century by the Irish Scots, the great invasion of the Picts and Scots aided by Saxons, reaching as far as London and Kent in 367, then more troubles among the Romans themselves, until in 407 these troops are finally withdrawn. That is about all the history—archaeology must fill in the picture.

The foundation of the map is the Ordnance Survey Physical Map of Great Britain, which brings out clearly the division of the island into Highlands and Lowlands by a line running north-east from the Severn Estuary and then due north along the eastern edge of the Pennine Chain. This marks off roughly the military from the peaceful occupation: nearly all the forts are on one side and nearly all the "villas" on the other.

A new and welcome feature is the delineation, by admirably chosen symbols, of the dense impenetrable forest and the more open woodlands which covered the country as the Romans found it—the first attempt at this restoration yet made for the whole island, and one that will be of the utmost value for the archaeology of all periods. All proved Roman roads are shown, and those not proved are not shown, even though they may be known to have existed: such is the case in Cornwall, where four Roman milestones have been found, though the roads themselves cannot be traced. They cover the whole country, reaching as far west as Exeter, and one running as far north as the Tay.

Altogether there are marked some four thousand five hundred miles of Roman-made roads, besides two of the pre-existing British ridgeways—the Icknield Way and the Harroway, which were undoubtedly used by the Romans.

The headquarters stations of the three legions were at York, Chester, and Caerleon-on-Usk. Taking the country as a whole no fewer than 90 detached permanent forts for land defence have been discovered; all in England are north of the Trent.

In the Cumbrian region there were 35 forts, the Peak country has 10, and Wales was held by no fewer than 23. In all this mountainous country there is hardly a villa; a few humble habitation sites have been found and a Romano-British village or two, besides caves where the finds indicate occupation by robbers or refugees. It is a wide and dreary network of roads strung with permanent forts ten or twenty miles apart. The occupation was evidently for mineral wealth; mines are found throughout—lead and copper, with one gold mine in South Wales.

But it was from Scotland that the chief danger to Rome arose. Hadrian's Wall from the Solway to the Tyne, 73 miles long and linking up fifteen permanent forts, though taken and reoccupied more than once, remained the frontier throughout. But, beyond it as far north as Aberdeenshire are found many remains of the unsuccessful attempts to occupy Scotland. Eighty miles north of Hadrian's Wall is the Scottish turf wall across the isthmus from Clyde to Forth. It was only 35 miles long and had no fewer than seventeen forts upon it, but it was nevertheless overrun twice, and was finally abandoned forty years after it was built. Along the two roads running into Scotland sixteen large temporary marching camps, not found elsewhere in Britain, point to great military activity. There are twelve permanent forts south of the Scottish wall and five beyond it, besides eight signalling stations. But all efforts were in vain, and the Emperor Severus died at York after his last campaign without effecting a permanent conquest.

Against the Saxon raiders a system of coast defence was set up in the fourth century under the Count of the Saxon Shore. There are the remains of ten strong stone-built fortresses on the east and south coasts reaching from Brancaster in Norfolk to Portchester at the head of Portsmouth Harbour. Five signal stations about ten miles apart guarded the Yorkshire coast between Huntcliff and Filey, and there is one at Old Burrow on the Bristol Channel.

The evidence of civil prosperity is nearly all in the southern half of Britain. The non-military inhabited sites in the north, even round such centres as York and Chester, are very few.

A continuous belt of thick forest, nowhere less than ten miles broad, stretched across the Midland clays from the head of the Severn Estuary to the edge of the Fens. This has always tended to act as a cultural division, and though the Romans drove their roads through it, and several occupation sites show that it was largely cleared, it still remained a great barrier to civilization; only two unfortified towns in England—Lincoln and Leicester—and three on the Welsh border are to be found north of it: the other twenty provincial towns, such as Exeter, Winchester, Canterbury, and London—mostly developments of the pre-Roman tribal centres—are all in the south.

Romano-British villages, large and small, are found all over the map; rare in the north, they cluster thickly over Salisbury Plain and the Dorset uplands. Here they are entirely agricultural, and are found as centres of the square-field "Celtic" cultivation. The light soil was suited to the implements of the period, and the scanty cultivation of later days has allowed their remains to be still traced. "Finds indicating permanent settlements"—in most cases, no doubt, the houses of small agricultural holdings—occur everywhere, though they are rare in the densest woodlands.

By far the most striking feature of the new map, however, is the record of the "villas"—important country houses, many of them showing evidence of being the centres of large agricultural estates. Their chief localities curiously correspond to favourite residential districts of the present day. They are found strung along the slopes of the North and South Downs, but not on occurs in the Weald; this was dense forest, and unoccupied except for its iron workings. In Hampshire, Dorset, Somerset, and Gloucestershire they abound. They are much fewer in East Anglia and the Southern Midlands but there is a thin line straggling up the north road to Lincoln and on to Yorkshire. There are about a dozen in that county, but none north of Catterick. Northern Wales has one and South Wales ten. A count shows 75 villas north of the forest belt and 325 to the south.

A curious feature is the absence of evidence of any important civil settlement in the south-west. Exeter is the most western town; there is no villa west of Seaton,

and only two villages and four inhabited sites have been found in the rest of Devon and Cornwall. There had been peaceful trade in tin and copper for centuries, but though there was much settlement in West Somerset the pleasant coasts of the British Riviera seem to have been unoccupied.

In the choice of a site the Romano-British landed gentry were far ahead of any of their successors down to quite modern times. Their villas are seldom far from a stream, and nearly all have a dry soil, a sunny aspect, and especially a good view. They chose a good corn-growing soil with open woodlands, which gave opportunity for sport. They were never far from a good road, and usually within a ride of a town, where their produce could be sold for the Continental or home market. They were not isolated; in many districts they are as close together as the country seats in the eighteenth century. They had every luxury, and even the poorer buildings show signs of comfort.

Southern Britain under Rome was a rich and civilized region, but it was a foreign civilization, and its roots had not struck deep enough to stand against the onslaughts from the North Sea. A large proportion of the villas show signs of fire and devastation.

J. P. WILLIAMS-FREEMAN.

Scotland.

Report of Scottish Board of Health.

THAT part of the tenth annual report of the Scottish Board of Health which deals with the work of the Board during the past ten years was summarized in our issue of April 20th (p. 740). The part of the report dealing with the year 1928 records several important developments. The output of houses of a working-class type for 1928 was 19,799, of which 5,517 were erected in county areas and the remainder in burghs; under the steel house scheme of the Government, which was completed in 1928, 324 houses were finished. In regard to town-planning, substantial progress has been made with the preparation of a regional scheme in the Clyde Valley area, while several local authorities in the neighbourhood of Aberdeen have combined in a joint committee to schedule an area of some 60,000 acres for building development. In Fifeshire, Ayrshire, Hamilton, Glasgow, Haddington, and Dundee plans have also been set on foot. Under the Highlands and Islands Medical Service Act considerable developments have taken place. Subsidies are paid to doctors in return for rendering medical service at low fees to the families and dependants of insured persons, and uninsured persons of the crofter and cottar classes, on condition that the doctors provide motor cars and, where necessary, motor boats, so that they might reach their patients expeditiously. Nursing services have continued to be subsidized, and two new nursing associations have been added to the grant list. In the course of the year a surgeon consultant was appointed for the county of Orkney by arrangement with the trustees of the Balfour Memorial Hospital, Kirkwall, this being the third appointment of its kind in the Highlands and Islands. In May, 1928, extensions to the Lewis Hospital, Stornoway, were provided by means of a grant, and were formally opened by the Under-Secretary of State for Scotland, thus removing the main difficulties under which the surgeon for Lewis and Harris has been compelled to work during the first four years of his service. The annual grant, amounting to £42,000, has been more than utilized, the excess of expenditure being provided from previous surpluses. It is stated in the report that 1928 was the first year in which the Preservatives Regulations in regard to food were in full operation, and that not a single outbreak of food infection was reported to the department throughout the whole year. The report points out that during the last few years there has been much activity in hospital construction, by way both of extensions and new buildings, and it contains a chapter which embodies the experience of the department in modern requirements for hospital planning and construction; this affords a model that may be useful to hospital managers, architects, and others. The deaths of children under 1 year in 1928 numbered 8,301, giving a death rate for these children of 86 per 1,000 births, which is 3 less than the rate for 1927, and 6 less than the mean of the preceding ten years. In the four large cities the rates for 1928 were: Edinburgh 75, Glasgow 107, Dundee 102, and Aberdeen 94, the Edinburgh and Aberdeen rates being the lowest recorded in these cities. While in 1919 there were 121 maternity and child welfare centres in operation in Scotland, by the end of 1928 there were 193. It is pointed out that this increase in numbers does not show the full increase in work, because at many centres there has been an increase in the number of sessions, while in some burghs local authorities have concentrated the work in large and modern premises, and closed a number of smaller centres. The number of practising midwives in Scotland at March 31st, 1928, was approximately 4,500, and during the year ended at this date midwives had attended 30,261 out of 89,167 births occurring in areas from which returns were received by the Central Midwives Board for Scotland. During the year under review there were in Scotland 7 maternity homes and 13 maternity hospitals, exclusive of institutions run for profit, and of these 11 were maintained by local authorities, with accommodation for 169 cases. A considerable amount of health propaganda work has been done by health weeks held under a number of local authorities, and at Edinburgh a health exhibition was organized by the corporation, at which 90,000 persons attended. The report draws attention to the need for further considering the subject of mortality and sickness associated with childbirth. During the year 676 deaths in Scotland were ascribed to conditions associated with maternity, as compared with 6,962 deaths due to cancer and 5,731 deaths due to pneumonia. The maternal deaths, though not relatively high, are believed to be largely preventable. It is pointed out that autogenous puerperal infection is probably rare, and that infection usually takes place from some source outside the patient. The increasing realization of the value of maternity homes is regarded as a favourable factor, and the opinion is expressed that every such institution should possess an administrative chief, necessarily a medical practitioner, who should lay down certain standards to which all persons working in the institution must conform. Reference is made to the desirability of notification of puerperal pyrexia in addition to the statutory notification of puerperal fever, which has operated since 1889. The conclusion is drawn that the provision of an ideal maternity service requires adequate training of both doctors and nurses, the recognition by both of their respective spheres and the need for co-operation, insistence on continuous ante-natal supervision, removal to hospital at the earliest moment of all complicated cases, and, finally, a hospital properly planned, staffed, and equipped. In regard to tuberculosis, a further fall in mortality is noted, the death rate per 100,000 of population in 1928 being 97, as compared with 99 in the year 1927. The figures for respiratory tuberculosis and other forms of this disease were respectively 68 and 29. The report deals with the work of the district medical officers appointed by the Board to adjudicate as to fitness for work, where a difference of opinion existed between the insurance medical practitioner and the patient or the society. An analysis of 5,000 consecutive cases, coming under these officers in Glasgow, was made. It was decided that of the male cases referred, 47 per cent. were incapable, while 53 per cent. were found capable of work; among the female cases 32 per cent. were found incapable, and 68 per cent. capable of work.

Poliomyelitis in Glasgow.

In 1928 there occurred in Glasgow an outbreak of poliomyelitis, confined to the months July to October, during which 91 cases were notified. This figure, points out Dr. James L. Halliday in his report,[1] is considerably in excess of those recorded during the previous five years, in which, though there was a slight progressive increase, the average

[1] *The Medical Officer*, April 13th, 1929.

number of cases was less than 9; the total number in 1928 was 112. Nearly three-quarters of the cases occurred in children under 5, a quarter of the total in the age group 1–2; infants under 1 year, and the age group 4–5, were much less affected. The incidence among males, except in the later age groups, exceeded that among females in the ratio 58 to 42. This ratio corresponds with that observed in other epidemics, though in the Glasgow epidemic the excess of females in the higher age groups was an unusual finding. The disease showed no tendency to pick out members of one social class rather than another. Only eight deaths occurred in the year, all during the outbreak proper, and there was no indication of a progressive increase in virulence. Only in two instances did groupings of infected cases occur—one of infants in direct contact with each other in a tenement building, the other of six children attending the infant and junior sections of a day school. A few possible abortive cases were discovered among those who had been in contact with cases of the fully developed disease. No evidence was found to inculpate the milk supply, or of concomitant disease among domestic animals in infected households. In 56 per cent. of cases the only early symptoms were vague feverishness and malaise; in 6 per cent. paralysis was the first evidence of illness, and in the remaining cases local symptoms, coryzal, bronchial, tonsillar, and gastro-intestinal, were prominent. In 79 per cent. of cases paralysis, mainly of the spinal type, occurred within seven days of the onset. Four months after the subsidence of the outbreak 43 per cent. of the cases of the spinal type showed more or less complete recovery from crippling.

New Municipal Hospital for Edinburgh.

Craigleith Hospital, situated on the northern outskirts of Edinburgh, has been reconditioned, and was formally opened as a hospital on May 7th by Dr. J. Parlane Kinloch, chief medical officer of the Department of Health for Scotland. Mr. James Duncan, chairman of the parish council, presided at the ceremony, and mentioned that the institution had been originally opened in 1868, having received various additions since that time. The hospital, which had a capacity for 120 beds, though there was a plan for its considerable extension, would be handed over next year to the town council under the Local Government Act. During the war it had been taken over by the Government as a military hospital, and had subsequently been used by the Ministry of Pensions. The reconditioning of the building had been effected out of money paid by the War Office, and this had been one of the last acts of the Edinburgh Parish Council. Dr. Parlane Kinloch, in declaring the building open, said that the achievement had been a great one, especially as it had been carried out at the time when the parish council and other local authorities responsible for health services had been engaged in examining the proposals of the Government for a far-reaching reform which envisaged the abolition of parish councils. The Edinburgh Parish Council had been imbued with the urge for social betterment, and had been enabled to provide for its successors this splendid example of hospital reform. A vote of thanks was accorded to Dr. Kinloch on the motion of Dr. J. W. Keay, medical superintendent of the hospital, and Sir Leslie Mackenzie, in proposing a vote of thanks to the chairman, remarked that they were standing at a point of new departure, and in the Local Government Act he saw one of the greatest documents in the history of Scotland, which constituted an excellent beginning for the twentieth century.

Home Relief to Incurables.

The annual meeting of subscribers to the Royal Society for Home Relief to Incurables was held in the City Chambers, Edinburgh, on May 10th. Bailie Shaw, who presided, said that this was one of the oldest benevolent institutions in the city. Applications for relief were received from patients in all parts of Scotland, and more than £5,100 had been paid in grants last year to 472 annuitants, while a further £1,700 had been distributed to beneficiaries under the Dunlop Cancer Fund. Mr. Alexander Miles, President of the Royal College of Surgeons, said that medical men had opportunities of seeing at first hand the benefits which flowed from this society, and they could appreciate that the relief was very real. The society had been in operation now for nearly a century and a quarter, and it brought great comfort to incurable persons in their own homes. The word "incurable" was, after all, only a relative term, and many diseases which fifty, forty, or even twenty years ago were looked upon as incurable were now almost completely under control. Tuberculosis, for example, was now looked upon medically as one of the most eminently curable of diseases, given satisfactory surroundings and conditions, with sufficient time to carry out treatment efficiently. There was also some hope for cancer, and within the last few weeks they had seen the magnificent response which the charitable public had made to the national appeal for money to secure a supply of radium for treatment of this disease. The value of radium in the treatment of cancer in many of its forms had been established, although there was much still to learn regarding cases in which it was appropriate, and as to the best methods of applying it. The time might come when the *raison d'être* of this society would cease, but meantime the need for financial support was urgent.

Irradiated Milk.

A demonstration of the value of irradiated milk in the treatment of rickets and other conditions was given by Dr. Chalmers Watson in the Royal Infirmary, Edinburgh, on May 10th to members of the public health department staff and others interested in child welfare. The lecturer pointed out that the value of irradiated milk had been indicated by Professor Scher of Frankfurt and others, but that little attention had been paid to the subject in this country. The municipal authorities in various German cities were now supplying irradiated milk as a curative and preventive agent. This treatment of milk had the advantage that the process of irradiation did not involve any chemical treatment or the application of heat or other process which would impair its nutritive value. The demonstration included a large number of *x*-ray photographs of children affected with rickets, illustrating the condition before and after treatment with irradiated certified milk, and appeared to show that irradiated milk exerted a marked curative influence on the disease, greater than that shown by exposure of the patient to ultra-violet rays and by other modern remedies. It was urged also that, from the economic side, treatment by irradiated milk showed a great advantage.

England and Wales.

The Home Ambulance Service.

THE growing complexity of diagnostic and therapeutic procedures in medicine and surgery, necessarily accompanied by an increasing tendency to remove patients from their homes to institutions where these procedures can be conveniently applied, has of recent years accentuated the demand for safe and efficient ambulance transport. In the voluntary hospitals of England and Wales outside London the number of in-patients treated rose from 461,834 in 1923 to 595,943 in 1927, and in the same period the number of out-patients from 1,969,194 to 2,467,140; the number of surgical operations under general anæsthesia increased from 367,905 to 534,436, the number of radiograms from 158,768 to 344,965, and of treatments in the electro-therapeutic and massage departments from £21,7[illegible] to 1,328,271. The Home Service Ambulance Committee of the Joint Council of the Order of St. John and the British Red Cross Society in its tenth annual report suggests that these figures, taken from the Joint Council's report on the voluntary hospitals, may serve to explain why the number of patients carried annually by the service has doubled since it was set up. It may fairly be claimed, says the report, that if the developments in transport are responsible for the increasing number of accidents, to transport also must be credited a very [illegible]

siderable share in the curing of disease. Since the service came into being the number of road accidents has risen by some 300 per cent., the number of persons killed or injured by road accidents in England and Wales during the year under review being over 150,000. To meet this situation the Home Service Ambulance Committee established a road service, with first-aid stations at many points on the main roads, and first-aid boxes at large numbers of dangerous places. The committee has succeeded in bringing the ambulance service into the closest possible relationship with the first-aid activities of the Order and the Society. Ambulances lent in the early days of the service for use in the larger towns have largely been replaced by municipal services, and the committee has thus been enabled to carry out its intention of extending its work further in rural areas. Thanks to increasing local support a considerable number of stations have been able to acquire ambulances of a more luxurious type than those provided by the committee; many units of the Order and the Society have in this way purchased ambulances without making any demands on the committee's funds. The committee's mobile *x*-ray service, designed to provide the physician and surgeon with facilities for conducting radiographic examinations of patients confined to bed, is being increasingly employed by the medical profession, and, though primarily intended for use in and around London, has on several occasions rendered valuable assistance much further afield. Many smaller hospitals have preferred to take advantage of this service rather than to install the smaller, and in the main unsatisfactory, type of *x*-ray sets. Radiograms prepared by the mobile *x*-ray service are submitted, together with the attending physician's notes of the case, to the British Institute of Radiology for interpretation, the considered opinion of a consulting medical member of the Institute being then forwarded with the radiograms to the doctor in charge of the case. The committee records with gratification the fact that its mobile *x*-ray service was employed for the examinations of His Majesty the King at Buckingham Palace, and that in one of the authoritative statements addressed to the medical profession the radiograms taken with this apparatus were referred to as excellent.

National Baby Week Council.

The National Baby Week Council in its report for the year 1928 records a greater demand for the council's services—for example, assistance in local baby weeks, health and baby weeks, health weeks, baby days, baby competitions—than in any other year since the war, and a remarkable increase in the requests for propaganda lectures, films, and literature. During the year there was a further extension of the health week movement, with continued co-operation between the council and the Health Week Committee. While regarding all aspects of the maternity and child welfare problems as important subjects for propaganda, the council, during 1928, urged that special attention should be given to immunization as a means of protecting young children against disease; prevention of maternal mortality —with special reference to ante-natal care and the provision of maternity homes and hospitals; and new developments in maternity and child welfare work. In connexion with the national baby week to be held this year from July 1st to 7th, the National Association for the Prevention of Infant Mortality has arranged for a conference to take place from July 2nd to 5th, at which the subjects for discussion are to be, the care of the child between 1 and 5 years of age; maternal mortality and morbidity; the establishment of special V.D. clinics for women and children in connexion with maternity and child welfare departments; and the suffering entailed on mothers and young children by prolonged waiting in out-patient departments of hospitals. During the same week the council is arranging for an extensive display of propaganda films, to which admission will be free by ticket, to be obtained from the secretary, 117, Piccadilly, London, W.1. The 1929 propaganda campaign will concentrate on the following three problems:

Practical measures which can be taken to combat maternal mortality, morbidity, and disability, with special reference to ante-natal and post-natal clinics, convalescent homes, holidays for mothers, and home helps. (2) What local authorities and parents can do to lessen the incidence and dangers of infectious diseases amongst young children. (3) The importance of teaching parentcraft and hygiene to school children. These subjects, the council advises, should find place in local and national propaganda programmes, in lectures, discussions, articles and paragraphs in the press, and in religious discourses.

The Work of Cripples.

The Devonian Association for Cripples' Aid, of which Dame Georgiana Buller is the chairman, is to hold what should prove to be an interesting exhibition at Exeter from October 30th to November 1st, under the auspices of the Central Council for the Care of Cripples in London and the International Society for the Care of Cripples in New York. The objects of the exhibition are to demonstrate the value of occupational therapy, to show how far cripples can compete successfully in the open industrial market, and to rouse public interest in the general question of the training and employment of physically defective persons. The promoters hope that the high quality of some of the work displayed will not only act as a stimulus to teachers and other workers acting in co-operation with orthopaedists in charge of crippled patients, but that it will have the effect, by showing what standard can be attained, of raising the at present uneven level of achievement aimed at by the disabled subject. Occupational therapy has the twofold advantage that it enables the patient to use and develop his available potentialities and to enjoy the moral advantage that comes from engaging in serious work and not merely in a consoling game. Some idea of the scope of the work done by cripples is afforded by the schedule of exhibits; in which there are twenty-nine classes, ranging from needlework to leather work, metal work, pottery, woodwork, manufacture of surgical appliances, and upholstering. This exhibition should go far to extend the demand for the products of cripples' industry and bring funds to the county organization for their care and cure.

The Tavistock Square Clinic.

The annual general meeting of the Tavistock Square Clinic took the agreeable form of a luncheon at the Hotel Russell on May 6th, when Sir Frederick Willis presided, and Dean Inge and Sir Philip Gibbs were the principal guests. Minutes, formal resolutions, and the usual agenda of such an occasion were suppressed, and, instead, the company listened to a witty address by Sir Philip Gibbs, whose theme was mainly neurasthenia as treated by contemporary novelists. Explaining, if not excusing, some features of modern fiction, the speaker said that if everybody was normal and balanced, not only would the Tavistock Square Clinic have no patients, but the novelists would have no characters. The novelist could not make much of those normal people who were facing up to life with courage and gaiety. Like the psychotherapist, he found his material among the abnormal, especially among those suffering from that nervous disturbance which was the price we paid for civilization and for getting away from primitive simplicities. The clinic, he said, was an institution for enabling people to get right in their minds, and he felt that it ought to be multiplied in many towns and cities, Tavistock Square remaining the headquarters. Sir Frederick Willis, from the chair, said that the annual report, which was printed and placed in the hands of the guests, was the record of a very fine piece of work. This clinic was started only eight years ago, because of the urgent need for treating cases of mental illness. It was a remarkable fact that the incidence of certified insanity in this country and also the recovery rate had not improved for a large number of years—the more remarkable because in other spheres of medical treatment great improvements had been made. One reason might be that other illnesses were now treated earlier than formerly, whereas early mental illness had gone untreated. The report of the clinic, made by the honorary director, Dr. Crichton Miller, stated that during the last twelve months there had been

5,447 attendances (4,582 adults and 865 children). There was no appreciable difference in the number of new cases, but the average length of treatment had increased. Adults who received treatment, as opposed to mere consultation or advice, had been seen, on the average, fifteen times. The number of cases referred to the clinic by hospitals had doubled in three years, and that of cases referred from police courts (mostly children) had nearly trebled. The honorary and acting staff, including the clinical assistants, numbered thirty-three doctors. From January last Dr. J. R. Rees assumed the duties of deputy director on a basis which enabled him to devote a large part of his time to active direction. The clinic is suffering from limitation of space, and schemes for extension are being mooted.

Treatment of Venereal Diseases in London.

The Public Health Committee of the London County Council recently considered, on a motion by Dr. Stella Churchill, the best means of putting into effect some of the recommendations of the Trevethin Committee, and the steps which might be taken to diminish further the number of defaulters under the venereal diseases scheme. In its report to the Council on May 7th the Public Health Committee described the attempt made already in London to reduce as far as possible the number of defaulters. Doctors and nurses at the clinics impress upon patients the necessity for regular attendance; the fares of necessitous persons to and from the clinics are paid; complaints relating to conditions likely to deter from attendance are investigated and remedied; and, most effective of all, five all-day treatment centres (a sixth to be provided next month) have been established. In 1921 the percentage of defaulters in London was estimated at 30; it is now about 16. Moreover, the ratio of attendances to new cases of venereal disease has increased from twenty-nine in 1923 to forty-six in 1928. It is felt that the very large number of non-venereal patients presenting themselves for examination—nearly 9,600 in 1928, as compared with 2,360 in 1917—indicates that the public are realizing more and more the serious effects of the disease. The conclusions of the Public Health Committee are that notification *per se* is of little value and might even be harmful to the efficiency of any venereal disease scheme; notification of defaulters followed by compulsory treatment raises questions as to forcing a certain line of treatment on an unwilling subject; there is difficulty in defining the standard of cure to be enforced; and the inequity is apparent of measures which operate in full degree on only one class—namely, clinic patients—affect only slightly defaulters among the patients of private practitioners, and leave untouched those who resort to quacks or make no attempt at all to obtain treatment, thus becoming a much greater danger to the community. It was thought that the inevitable result of any measure of notification would be an increase in the number of patients giving false names and addresses, and delay in reporting for treatment. The committee feels that in view of the continuous improvement in the attendances per patient there is at the moment no urgent necessity for the introduction of measures of doubtful wisdom such as compulsory notification.

Ireland.

Appointment of M.O.H. for County Galway.

AT a meeting of the Galway Board of Health and Public Assistance a letter was read from the Department of Local Government and Public Health suggesting that the board should seriously consider the advisability of recommending the county council to appoint a county medical officer of health, and expressing the view that the board would incur a grave responsibility if it postponed dealing with this urgent matter. Dr. Sterling Berry, one of the department's medical inspectors, who attended the meeting, pointed out that the incidence of infectious disease in the county was far too high. During the past two years 79 cases of enteric fever and 184 cases of diphtheria were reported to his department from the county of Galway. These figures of disease, due to preventable causes, and pointing to extensive disregard of proper sanitary precautions, were much in excess of those from other counties in the Free State, and indicated clearly the necessity for a centralized county control of infectious disease, especially when it was remembered that money spent in maintaining institutions for segregation and treatment would cover the cost of beneficial schemes of public health improvements. Dr. Berry pointed out that where county medical officers of health had been appointed persons were being scientifically examined as to their susceptibility to diphtheria and immunized against the disease. In Connemara there was a chronic smouldering infection of typhus fever, with periodical outbreaks, which exacted a heavy cost both in human life and in money. Modern sanitary methods applied to Connemara would eradicate this dreadful disease, which progressive communities had succeeded in stamping out. During the year 1926 a widespread outbreak of encephalitis lethargica occurred in county Galway, about one hundred persons being affected. These cases were not reported to the Minister, and as there were no local facilities for co-ordinating supervision, a valuable opportunity for studying the disease, and perhaps preventing further outbreaks, was missed. Dealing with the question of school inspection, Dr. Berry stated that a number of children through the county suffered from dental defects, adenoids, septic tonsils, malformations, and defective vision, and that the detection and early treatment of such conditions were essential if these children were to become efficient and self-supporting citizens. Defects discovered in children could be treated in their excellent county hospital by the staff of experts attached to it, and half the cost of such treatment would be met by the Government. The organization of inspection of school children under a scheme of school medical service was one of the chief duties of a county medical officer of health. The care of expectant and nursing mothers and the inspection of midwives (now a statutory obligation of the Board of Health) were urgently required in county Galway, and would come within the province of the county medical officer of health. The port of Galway was becoming an important centre for immigration and emigration, and it was now absolutely necessary that the incidental operations, particularly in regard to immigration, should be controlled by an expert medical officer of health. The cost of a county health service would not really be an added burden on the rates, as so many of the health activities ranked as recoverable on a 50 per cent. basis. After a discussion it was decided to refer the appointment of a county medical officer of health to the county council, the body which was responsible for making the appointment.

School Inspection in County Kildare.

At a recent meeting of the County Kildare Board of Health the county medical officer of health, Dr. Harbinson, reported that during the month of March 749 children had been inspected in ten schools. The following are the particulars of the defects found: suffering from defect, 564; suffering from more than one defect, 239; free from defect, 185. Dental defect, 400; defective vision, 89; tonsils and adenoids, 139; malnutrition, 53; uncleanliness, 65; bronchitis, 16; heart disease, 7; suspected phthisis, 1; tubercular glands, 8; postural defects, 30. Thirty-three children were inadequately clothed and shod; and 389 had been vaccinated. The figures correspond closely with those disclosed at the previous inspection.

County Limerick Infirmary.

At the meeting of the Committee of Management of the County Infirmary, Limerick, a vote of condolence was tendered to the relatives of the late Dr. W. A. Fogarty, and regret expressed at the resignation of Dr. T. F. Mulcahy as visiting surgeon to the institution. The committee appointed Dr. D. Corboy and Dr. C. Moloney to vacancies in the visiting staff caused by the death of Dr. Fogarty and the resignation of Dr. Mulcahy.

Correspondence.

THE DISTRIBUTION OF RADIUM.

SIR,—The question raised by Mr. Souttar (April 27th, p. 787) requires urgent consideration and decision, as it appears that we are about to spend a vast sum of money on the purchase of a much-needed additional supply of radium. It is well to recall that a quarter of a century ago, after the discovery and therapeutic application of radium, when small quantities were in the hands of many, a wave of enthusiasm swept over Europe and America because the immediate results of the treatment of malignant disease were so favourable that the cancer problem was regarded as solved. In the course of a few months, however, when it was found that the growths reappeared, reaction set in, and radium was relegated to the heap of discarded cures. In the intervening years, in the hands of patient workers, radium has won a definite place for itself in the treatment of cancer, but the danger of enthusiasm again threatens to flatter immediately, but to destroy ultimately, the position won.

To ensure against the repetition of history two conditions are essential: (1) to gain the confidence of the public. They should not be misled into thinking that all cases of cancer can be cured by radium; it would be truer to state that our knowledge of the action of radium is incomplete, but that in the hands of the most experienced workers the results of irradiation are so good that in some cases operation has been abandoned in its favour. To this end the publication of lectures and papers containing sweeping statements, often inaccurate and frequently tinged with the bias of enthusiasm, should be deprecated. It is rare to attend a discussion on the treatment of cancer without hearing reports of the immediate results of radium therapy or the results after one or two years, neither of which are of value in assessing the importance of radium. We should encourage a self-denying ordinance in which no results should be published for five years.

(2) The second condition naturally follows the first. If the public give us their trust in the matter they are entitled to demand that they shall only be treated by the most experienced workers, and therefore the radium should remain in the control of the few until such time as disciples have gained sufficient knowledge and experience.

I agree with Mr. Souttar that radium centres should be established. They should be set up in relation to the population served, preferably in modern hospitals possessing recent *x*-ray plant. Each centre should serve the neighbouring two, three, or four counties, where distances would be relatively small and therefore subsidiary centres unnecessary, and there should be a sufficient number to cover the whole of Great Britain. The work should be under direction to ensure uniformity of technique, for haphazard work leads nowhere. The staff of the Soho Hospital for Women have adopted a uniform plan for the treatment of cancer of the cervix, and I believe St. Bartholomew's have similarly planned treatment of cancer of the breast; in this way considerable experience will be gained of particular methods. These centres must undertake the treatment of the well-to-do class; the family doctor would be at no greater disadvantage than he is now when he hands over his patient for operation. Fees should be charged for the radium in addition to the surgeon's fee, and in this way insurance, repairs, and new apparatus would be provided for.

I do not agree with Mr. Souttar that the future lies with emanation, at any rate until we have gleaned much more knowledge than we possess to-day. There is no doubt that it is financially safer to use seeds, but when we recollect that they lose half their strength in 3.85 days, and a further half of the remainder in the same time, it requires a large assumption to say that one obtains the same result, even though adjustments be made, as when we expose the growth to the salt, which for practical purposes remains uniform.—I am, etc.,

SIDNEY FORSDIKE, M.D., F.R.C.S.

London, W.1, May 6th.

THE RELATIONSHIP OF ALASTRIM (VARIOLA MINOR) TO SMALL-POX (VARIOLA MAJOR).

SIR,—Dr. John A. Graham's letter in your issue of May 11th (p. 881) cannot be allowed to pass unchallenged. He describes an experience of his, "some years ago," where at a farm in South Africa there occurred an outbreak of alastrim or "mild small-pox" (a most unscientific name) in which most of the cases were of the usual trivial character, but two were more severe, and one of these, the father, had "a very severe confluent attack, from which he died." Dr. Graham sums up: "Evidently the mild disease, like others of the exanthemata, may become intensified in virulence *and pass into variola major*." (Italics added.)

In this facile manner Dr. Graham settles, apparently to his own satisfaction, the crucial point which has been exercising experts for years!

Unfortunately Dr. Graham makes the common mistake of failing to appreciate the distinction between clinical type and strain of variety, a mistake easily accounted for by the present unscientific use of the term "severe small-pox" as a synonym for variola major, and of "mild small-pox" for variola minor. The fact is, of course, that we may have mild cases of variola major and severe cases of variola minor, the distinction between the two affections being that a case of variola major, whether mild or severe, tends to propagate a severe variety of small-pox, whilst a case of variola minor, whether mild or severe, tends to propagate a mild variety of the disease.

Severe confluent variola minor.

Dr. Graham apparently takes it for granted that because his case was a severe one it was necessarily one of variola major. I submit that the evidence he adduces all points to the case having been one of variola minor, and, if so, then of course his thesis that the minor form may change into the major collapses entirely. The only way to prove that an individual case of small-pox, however severe or however mild, is variola major or minor is by tracing the history of a series of cases arising from the case in point. In practice, so long as one is only dealing with a single variety not much difficulty is likely to be experienced, since the average severity of the two affections is so different.

I would like to parallel Dr. Graham's case with a very severe confluent case of small-pox in a man which occurred in Leicester in 1925, in the course of an outbreak of undoubted variola minor. The man was acutely ill, and for a time I was anxious for his life. He was infected by his wife, who had a typical trivial attack of variola minor, with less than a score of lesions altogether. Even if the man had died there would have been no question of his being a case of variola major. A photograph of this case, showing the confluent nature of the eruption, is reproduced here. I have no doubt others who have had experience of variola minor could adduce similar cases.—I am, etc.,

Leicester, May 12th. C. KILLICK MILLARD.

PLACENTA PRAEVIA.

SIR,—As the subject of placenta praevia is to be discussed at the Annual Meeting this year of the British Medical Association it seems opportune to suggest that the terminology of the subject might be reviewed and, if possible, standardized. The difficulty lies with the two types described variously as lateral and marginal. Whitridge Williams and Fothergill, to quote two writers, describe the type in which the placenta partially covers the os as lateral, and the type where the placenta merely

extends on to the lower uterine segment as marginal. Other writers, Johnstone and Fairbairn among them, refer to the former as marginal and the latter as lateral. This has given rise to considerable confusion in the past, especially in the teaching of students, and must inevitably do so at the Annual Meeting, particularly when treatment is being discussed.

It is perhaps unfortunate that the condition cannot be described under the two headings, central and lateral, but the treatment is so dependent on the relationship between the edge of the placenta and that of the cervix, at the time at which it has become necessary to intervene, that it would be essential to describe, as a subdivision of the second, a third type—namely, that in which the edge of the placenta does not reach the edge of the cervix, and the one, incidentally, in which artificial rupture of the membranes and application of a binder is adequate treatment.

As lateral and partial have already been used to describe the same or intermediate type may I suggest that the term lateral be dispensed with entirely in favour of the more descriptive term partial, and that the three types be referred to as central, partial, and marginal? One recognizes, of course, that any classification must refer only to the state of affairs at the time of examination, since a case appearing central when the dilatation of the os is one finger may prove to be partial when dilatation has proceeded further.—I am, etc.,

E. A. GERRARD,
Resident Obstetric Surgeon, St. Mary's Hospitals, Manchester.

May 8th.

COLLES'S FRACTURE.

SIR,—The innate modesty of the general practitioner often stays his hand from reporting the results of treatment. The paucity of his cases as compared with the many of the surgeon associated with a hospital has a very deterring effect. I have, however, been so much interested in the articles on Colles's fracture that have appeared recently in this *Journal* that I have been tempted to add my personal experience, which your readers can evaluate from their own.

During the first forty years in general practice the methods taught in the colleges, practised in the hospitals, and gleaned from literature, present and past, were religiously followed. The results—pain, deformity, dysfunction—were, only too often, exasperating to both patient and surgeon. About 1914 an innovation came—whence or how is unknown, as I had never heard or seen any reference to it—but the results from it have been most gratifying to both patients and surgeon. For forty years I disliked treating a Colles's fracture, but since 1914 my attitude has been completely changed. The method now in use is as follows.

Complete surgical anaesthesia is induced. The assistant grasps the patient's forearm firmly, while the surgeon clasps hands—right with right and left with left—as in handshaking. Sufficient extension is made to reduce any impaction that may exist, and when free from any entanglement the lower end of the ulna is used as a fulcrum, and the hand bent downwards until the distal fragment hangs over the end of the radius, much like a suspended "corner stone" that is about to be laid. When a proper alignment has been made by the thumb and fingers of hand clasping the wrist, the hand is raised, and the muscles jerk the fragment into place with a "snap." The contour of the wrist is carefully compared with that of the normal wrist. The hand is freely moved to ascertain that it can function normally. Plain, guttered, or plaster splints may be used. These are removed daily, or at longer intervals. Electrotherapy can hasten functional restoration, as also massage and sunshine. No restriction is placed on moving the fingers, while the surgeon can move the hand in all directions after the second or third day, and within three or four weeks the patient may resume his or her vocation.

Two recent cases show the results to be expected under normal conditions.

A young pianist fell about twelve feet and struck a cement pavement with right hand extended: excruciating pain followed; the swelling and classic deformities were very pronounced. The pain was promptly relieved by this procedure. The patient resumed piano-playing within a month, and neither patient nor parents could detect any difference in the wrists.

A woman, over 60 years old, and weighing 190 lb., tripped on the doorstep and fell about six feet on to a cement pavement with her left hand extended. Excruciating pain, swelling, and very marked deformity ensued. The pain was quickly relieved, and the patient resumed knitting on the third day; within a month she was strenuously engaged in washing, ironing, and at other work. She says, "The broken wrist is just as strong as the other, and my friends cannot tell which one was broken."

The surgeon must not use the ulna as a fulcrum to reduce the impaction, since a serious complication could easily be produced by excessive pressure.—I am, etc.,

Toronto, Canada, April 24th. JOHN HUNTER.

SIR,—In the course of several years in general practice and as casualty officer in a large general hospital I have found the following mechanism of reduction the best, whether general anaesthesia was available or not. I will describe the reduction of a right Colles's fracture; if it is in the left forearm, the other hand of the operator should be used from the other side of the patient.

Lay the patient on a couch, stand at his right side facing his feet, and take the injured limb under the left arm, gripping it against the side by the elbow and resting the injured part on the left hand, so that the thenar eminence fits into the hollow proximal to the distal end of the broken radius, and the fingers support the patient's palm. Now proceed to reduce the fracture by pressure with the right thenar eminence, the right fingers and thumb steadying the injured hand and, as soon as the impaction is reduced, applying the necessary downward traction, to correct the dinner-fork deformity, by a sliding forward and downward movement. The limb can be held under the arm while the splint is being applied and adjusted, a great advantage when one is working single-handed.

This is really an adaptation of Sir Robert Jones's thenar eminence method, but is performed the other way round, with the opposite hand, looking away from instead of facing the patient, and has the additional advantage that the limb can be held definitely steady even if the patient is hysterical and no anaesthetic is available.—I am, etc.,

H.M.S. *Flinders*, May 1st. T. WILSON FROGGATT.

THE SUBCUTANEOUS TUBERCULIN TEST.

SIR,—I cannot answer the question put by Dr. J. Stacey Dick in his letter on May 4th (p. 831) as to the value of tuberculin injections in the diagnosis of renal tuberculosis, because when I meet a case suggestive of renal tuberculosis I send the patient to a hospital where cystoscopic examination and tests can be applied, with a view to finding which kidney, if any, is tuberculous; I have depended on the report of the urologist for the diagnosis. However, in cases referred to me as tuberculous peritonitis, with or without a note of interrogation, I have used in doubtful cases test doses of tuberculin given subcutaneously, and have made my diagnosis in accordance with the result of the test. In no case so far has the subsequent history of the case shown the diagnosis so made to have been wrong.

In connexion with the diagnosis of pulmonary tuberculosis I have had a much more extensive opportunity of observing whether the test by subcutaneous injections of tuberculin is to be relied upon or not. On looking up my records I find that my assistants and myself have applied this test in 726 cases where there were symptoms and/or signs pointing to pulmonary tuberculosis as a possibility. These cases have been spread pretty evenly over the last sixteen and a half years. As a first test dose we give an injection of 0.0002 c.cm. of old tuberculin human (T). If no local or temperature reaction follows we go on to give doses of 0.0004 c.cm., 0.0008 c.cm., 0.0016 c.cm., 0.0032 c.cm. and 0.0064 c.cm. If none of these injections produce a decided reaction, we inform the patient and his friends that he is not suffering from tuberculosis.

In all the 726 cases the sputum, when available, had been previously examined and no tubercle bacilli found; the patient was afebrile, or had become so by a preliminary resting in bed. Of these patients 435 reacted and 291 did

:ot—that is, 60 per cent. reacted and 40 per cent. did not. :o be able thus definitely to eliminate 40 per cent. of our therwise doubtful cases is extremely valuable. As Pro- essor Lyle Cummins has found, the intracutaneous test ·ould only eliminate about 10 per cent.

It will naturally be asked: Has the subsequent history f the 291 persons pronounced not to be suffering from uberculosis justified such a pronouncement? I consider hat it has. In 5 out of the 291 negative cases tubercle acilli have subsequently been found in the sputum. ience we do not say that those who have not reacted to :x subcutaneous test doses are immune to tuberculosis for fe, but only that at the time of the testing they were ot suffering from it. The smallness of the proportion of ose who have afterwards been found with tubercle bacilli i the sputum appears fully to justify this. Of the 435 ho reacted to the test doses 62 have later been found to ve tubercle bacilli in the sputum.

We advise all the reactors to spend the necessary time ther to go to a sanatorium or to attend one of our spensaries for a course of tuberculin.—I am, etc.,

JOHN R. GILLESPIE,
May 7th. Tuberculosis Medical Officer, co. Down.

MEDICAL WOMEN AND THE POST OFFICE.

SIR,—*The attention of the council of the Medical* omen's Federation has been drawn to the fact that there e certain appointments now vacant in the Post Office edical Service which are being offered to medical women salaries which are grossly inadequate. It is felt that iblic attention should be directed to the matter.

Two half-time appointments in the Savings Bank and oney Order Departments, involving four hours' work on : mornings a week (three weeks' holiday) and carrying th them no pension and no sick pay, have been offered to edical women at salaries of £150 per annum. Under essure this sum has been raised to £175. The original ure works out at a little over 2s. 4d. per hour, and the ended one at 2s. 9d. per hour. This scale of remunera- n, we are sure it will be agreed, is an insult to the men who are expected to accept it.

The Post Office is already notorious for the underpayment its women medical staff, and as being the only Govern- nt department in which unequal payment exists between male and female medical officers. But such flagrant derpayment as in the present instance—at the rate of 50 per annum with no sick pay and no pension—passes bounds of belief. The Federation sincerely hopes that next Government, whichever party may be returned to wer, will set itself to rectify this unjust and intolerable te of affairs.—We are, etc.,

CATHERINE CHISHOLM, President.
CHRISTINE M. MURRELL, Past-President.
A. E. SANDERSON CLOW,
ALISON M. HUNTER,
L. MARTINDALE, Vice-Presidents.
JANE H. WALKER, Honorary Treasurer.
MABEL L. RAMSAY, Honorary Secretary.

ondon, W.1, May 10th.

THE GENERAL PRACTITIONER AND HOSPITAL TREATMENT.

SIR,—Dr. Edwards's letter on May 4th (p. 832) under s heading is of great interest. The grievances of the eral practitioner and those of the honorary medical er are, indeed, identical; the first does not want lose his chronic patient, and the second cannot get of him. The patient so often prefers the flavour of eleemosynary "mist" be it "repped" ever so often, the authorities will not help the honorary medical er to reduce attendance statistics. Providing steno- phers for the medical staff would increase the value hospital's work tenfold, but it would not look so well he annual report as a few thousand extra "rep. mists."

Dr. Edwards referred to the literature accompanying the eat on his homeward journey; let us now analyse that which attends him to the out-patient department. It falls into five categories.

1. Request for opinion, containing useful note on early symptoms, previous treatment, etc., 10 per cent.
2. Request for opinion *tout court*, 40 per cent.
3. "Mrs. Jones has ringworm, for *x*-ray treatment, please" (!), 5 per cent.
4. Printed certificate that "Mrs. Jones is suffering from so-and-so and is recommended for hospital treatment," 15 per cent.
5. Visiting card, 30 per cent.

The whole work of the hospitals could at once be put on a better basis altogether by creating but one vacancy in the hagiology of the voluntary system. Abolish subscribers' letters. Their only function is to give an occasional "vice-president" or "governor" a feeling of patronage for his money, and they are quite useless in ensuring that the right kind of patient receives attention. Replace them by books of vouchers issued to each general practitioner, one kind entitling him to send a patient for one consultation in the out-patient department, a second kind stating that the patient has no means and is suitable for free treatment, and a third kind for emergencies of all kinds. No patient, saving accident cases, should receive attention without production of one or other voucher. Where special treatment was advised, or even a further examination desired by the honorary medical officer, an out-patient's card could be enclosed in his letter to the general practitioner for him to hand to the patient if he approved of such arrangement.

In this way could the honorary medical officer be spared, and the hospital prevented, from competing with the private practitioner.—I am, etc.,

Brighton, May 7th. J. H. T. DAVIES.

SIR,—Dr. W. Edwards in his letter (May 4th, p. 832) complains that some hospitals "have no organization for acting in a consultant capacity" with practitioners who send them patients for an opinion or for special treatment. His experience is most unfortunate; it is the usual practice of surgeons and physicians in charge of out-patient departments to reply in person to letters concerning cases sent by doctors, or to ask their house-surgeons or house-physicians to do so.

When a patient is admitted to the Royal West Sussex Hospital the following notice is sent to the private practitioner:

Dear Sir,
I beg to inform you that your patient.....
of..... .....is to be admitted under the care of Dr.....

When the patient is discharged the following notice is sent, with the particulars duly entered.

Date.....
Name and address of Patient.....
Name and address of Doctor.....
Surgeon.....
Physician.....
Diagnosis.....
Operation or Treatment.....
X-Ray Report.....
Pathological Report.....
Cause of Death and date.....
Post-mortem Report.....
Remarks.....
(Signed) .....House-Surgeon.

If this method were generally adopted in relation to out-patient cases as well as in-patients, it would, I think, meet the requirements of most doctors.—I am, etc.,

Chichester, May 6th. ARTHUR M. BARFORD.

A RELIABLE TEST FOR PROGRESS IN HEARING.

SIR,—It was truly stated in your interesting leader on chronic deafness in the *Journal* of May 11th (p. 864) that the patient might think he heard better, although to our tests his hearing was as poor as before. It is also true that the patient thinking he hears no better (generally on the authority of his wife) may prove, on fair and unbiased testing, to have undoubted increase of hearing power. There is one test, however, which I think incontrovertible. *If other people have spontaneously made the statement that the deaf person hears better*, I think we may safely assume that he really does so.—I am, etc.,

London, W., May 14th. JAMES DUNDAS-GRANT.

ASTHMA.

SIR,—Before studying any disease it is often wise to become familiar with the physiology of the subject. The admirable physiological experiments of T. G. Brodie and W. E. Dixon have been lost in obscurity by the fact that they are to be found only in those libraries which store the *Transactions of the Pathological Society of London*. In the volume of 1902–3 their work is published. If you, Sir, could see your way to reprint this all-important but very inaccessible document it would be a great service to all who are interested in asthma. I suggest this because the more I read of and study the various aspects of this difficult subject, the more I realize that no one can even begin to understand it unless he is fully grounded in the fundamental facts which no one can dispute.—I am, etc.,

London, W.1, May 4th. H. MORTIMER-WHARRY.

*** We hope to publish in the near future an adequate abstract of the paper by the late Professor T. G. Brodie and Professor W. E. Dixon, which appeared in full, with illustrations in the *Transactions of the Pathological Society of London*, vol. liv, pp. 17–39.—Ed., *B.M.J.*

MODERN ASPECTS OF NEPHRITIS.

SIR,—I read with interest Dr. Langdon Brown's paper on nephritis (May 4th, p. 797) and was especially interested in his plea for recognizing high blood pressure in chronic nephritis as a compensatory phenomenon, to be preserved rather than artificially reduced, a point which I also endeavoured to make in my address on the treatment of nephritis (April 20th, p. 726). I should like, however, to criticize some minor inconsistencies and misstatements.

Dr. Brown stresses the septic factor in the etiology of acute nephritis, but he omits to follow up this obvious indication in treatment; he makes no mention of the importance of removing such foci. Referring to Epstein's views, he states that "the *lipoids, especially* cholesterol, accumulate in the blood . . . ," but later, in criticizing Epstein that "there seems little justification for his embargo on fats, since it is *only* cholesterol that is concerned . . ." (the italics in each case are mine), also that "Epstein is not consistent in this, since he allows eggs. . . ." If Dr. Brown will refer to Epstein's papers (for example, *Amer. Journ. Med. Sci.*, 1917, ii, 638) he will see that it is only egg *white* which is used.

Further, Dr. Brown refers to "Volhard's introduction of the term 'nephrosis,'" and suggests that it should be limited to "toxaemic kidney in which there are merely degenerative changes . . . without any inflammatory reaction." The term was actually introduced by Müller, as Volhard himself states (*Die doppelseitigen hämatogenen Nierenerkrankungen*, 1918, p. 322), to include all non-inflammatory kidney diseases, and was limited by Volhard to primarily degenerative cases.

I may say that I am not a whole-hearted supporter of Epstein's views, and agree that the term "nephrosis," though often useful, is not ideal. Nevertheless, I think it is considerably more justifiable than the term "hydraemic nephritis," which Dr. Brown retains, since we find in chronic glomerulo-nephritis "according to some authorities, a marked hydraemia, and yet these cases run, as a rule, until the end without any edema, while cases of nephrosis with marked edema do not show any real hydraemia." (Epstein, *Amer. Journ. Med. Sci.*, 1922, i, p. 178).—I am, etc.,

Sheffield, May 4th. ROBERT PLATT, M.D., M.R.C.P.

INCUBATION PERIOD OF SCARLET FEVER.

SIR,—A patient, aged 17, had a tooth extracted under gas, which caused such severe haemorrhage that she was confined to bed for ten days, during which period there was no possible contact with infection. On the eleventh day she developed definite scarlet fever, which was followed by peeling. Does this not suggest that the recognized period of incubation (that is, one to eight days) is not of sufficient length?—I am, etc.,

Southbourne-on-Sea, Hants, May 10th. S. J. HAYLOCK.

PYORRHOEA ALVEOLARIS.

SIR,—Perusal of the letters of Mr. Badcock (February 23rd, p. 373) and Mr. Porter (March 16th, p. 525) gave me the curious illusion of having returned to the late nineties when, as a student, I was taught that decayed teeth do not decay and that pyorrhoea is a fine disease. I am glad to recognize that this was an illusion and that the last thirty years have brought us some fresh knowledge of these conditions. I can go a great part of the way taken by Mr. Badcock and Mr. Porter, but I think patients might well be encouraged to use the small round brushes employed by dental surgeons for brushing their teeth. They are efficient and much more easily kept in a sanitary condition than is the ordinary toothbrush of commerce. They are so cheap that they can be frequently discarded; but it is not every patient who has sufficient nous to acquire the technique of their proper use.

There are, in effect, two quite distinct types of pyorrhoea; one is a septic or dirt disease which can be prevented, and in early cases cured, by scaling and efficient tooth-brushing. This is the more prevalent type of the disease; but the other, the infective type, occurs in mouths that are kept scrupulously clean, and is much more frequently associated with systemic infection, arthritis and anaemia. This type of case is comparatively rare in the ranks of the well-fed, often overfed, opulent classes who frequently get out beyond the smoke pall of the great towns. Besides, having been told by Mr. Badcock that it is all a question of cleanliness these patients may be ashamed to return to him, and to show that the condition has gone from bad to worse. In fact, mere local treatment is quite unavailing in these cases, in which there is an insidious and dangerous infection, like that of tuberculosis. It cannot be cured by extracting the teeth, a traumatic procedure calculated to open up new tracts of infection into the alveolar circulation and frequently followed by deplorable results. The disease can only be conquered by the patient's own defensive reactions; and the reinforcement of these is almost the whole objective of rational treatment.

These are essentially cases for the doctor rather than the dental surgeon; the chief thing that the latter is called upon to do is to realize the importance of the condition when he sees it and to get the diathesis treated. Can not medical practitioners be induced to take a renewed interest in a very important condition which during the past thirty years has been relegated to the hands, the hands rather than the brains, of dental surgeons?—I am, etc.,

London, W.1, April 29th. F. TALBOT.

THE ABUSE OF NARCOTICS AND SEDATIVES.

SIR,—The unfortunate and widespread habit of drug-taking has reached such an acute stage that it is over time we should unite in order to lessen what may be a national curse. It is far from uncommon, for instance, to meet women who have been taking, on medical advice, some drug such as luminal for months. These patients are, as a rule, in a hopeless state, both mentally and physically. The continual use of this and other drugs—medinal, adalin, chloral, trional, veronal, etc., should never be prescribed without due thought and care.

The very fact that many narcotics are capable, if given in small repeated doses, of exciting the nervous system should in itself call for discrimination. Loss of self-control and will power are common effects of drug-taking. An energetic action may be necessary in order to save a patient from becoming a wreck, so there is surely only need for a word of caution. I have seen a large number of these cases which are slowly but surely approaching the "borderline" through careless prescribing; hence this letter. One can do much by the use of suggestion in general treatment. The physical condition is so often poor, a warning in itself against undue use of drugs. Neurasthenia, insomnia, hysteria, and nervous debility are conditions which are always calling for care and attention, and, further, will often respond to general treatment where narcotics and sedatives have failed.—I am, etc.,

Canford Cliffs, April 30th. FRANCIS G. BRETT.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

Prorogation: The King's Speech.

THE King's Speech proroguing Parliament, which the Lord Chancellor read in the House of Lords on May 10th, referred to the British Government's decision to take steps to accept in the King's name the Protocol prohibiting chemical and bacteriological methods of warfare. Mention was made of the confidence held by Ministers that the reorganization of relations between the State and local authorities would enable better provision to be made for the health and welfare of the people. Allusion was made to the reorganization of the Scottish Department of Health. The Speech further said:

"My Ministers have initiated an inquiry into the radium requirements of the country in the light of the knowledge and experience gained as to the importance of radium in the treatment of cancer, and in accordance with the recommendation made to them they have agreed to contribute to a fund for the acquisition of a stock of radium. It is My earnest hope that this action may prove a substantial step forward in the campaign against one of the most distressing maladies known to mankind."

Acts which received the Royal Assent on May 10th before the prorogation of Parliament include the Pharmacy Act, 1929, Artificial Cream Act, 1929, Infant Life (Preservation) Act, 1929, Age of Marriage Act, 1929, and Acts confirming provisional orders of the Ministry of Health.

The Scottish Estimates

On May 7th the House of Commons discussed the vote for the Scottish Department of Health. Dr. ELLIOT said that the estimates for it this year were up by about £260,000. The figures for infant mortality were 86 per 1,000, compared with 89 per 1,000 last year. The average of infant mortality for ten years past came out at about 92 per 1,000, so that there had been a very important saving in life. The rate, however, was not satisfactory compared with those of England and other countries in the Empire. Maternal mortality remained high, both in Scotland and in other countries with a high standard of living. It did not appear to yield to a general advance in the prosperity of the country as did infant mortality. The death rate from tuberculosis was 97 this year, as compared with 99 last year and 116 in 1924. Those figures compared favourably with world figures. Health benefit payments showed a disquieting tendency to increase to successively higher levels. In the first four months of last year the total cash benefits paid out amounted to £75,000, and for the first four months of this year to £981,000. In that morning's issue of the *Times* he had given an account of some tests that nature had carried out in East Africa, where two tribes had been found living under similar conditions, one of whom consumed a great deal of milk while the other did not. Tests carried out at Aberdeen gave similar results to those in East Africa, and showed that there was a marked improvement in the health of school children by the addition of a small amount of milk to their diet. Scotland was fortunate in possessing a close and intimate link between the Department of Health and the voluntary hospitals and medical schools associated with those hospitals. About £68,000 per annum was being spent on the Highlands and Islands service. Without this service the inhabitants of the Highlands and Islands of Scotland would be without proper medical treatment. The fund, however, had been living on its savings for some time, and it would be the duty of the new Government after the General Election to maintain and enlarge the provision made for it.

Dr. DRUMMOND SHIELS said that in times of stringency other things should be sacrificed before the public health services. The 1,000 houses that had been provided in Scotland towards slum clearance were a miserable contribution. He was glad to notice the emphasis in the report of the department on the importance of dealing with children between the ages of 2 and 5 years in nursery schools. These nursery schools might provide facilities for inculcating habits of discipline and so on, but their object was to remove children from playing in the gutter and to give them a chance of having physical defects remedied. School medical officers and other medical men were sure that bad tonsils, adenoids, and similar defects, which were such a nuisance and cause of anxiety to parents during the ordinary school life of the children, had their beginning at that period of life, and if they were promptly dealt with a great improvement would result in the health of the children. There were 350,000 such children in Scotland, and only by a system of nursery schools could the problem be tackled. He did not know what the position in Scotland generally was, but in Edinburgh plans had been made for starting one nursery school in the immediate future. A big programme of nursery schools would be put into operation if the Labour party came into power after the election. The Under Secretary for Scotland had dealt interestingly with the problem of maternal mortality, child welfare, and infant mortality, all of which were more or less grouped together. He was glad to notice in the report the figures relating to ante-natal clinics and childbirth. These showed that, taking an average of four years from 1924 to 1927, in the case of women who received ante-natal attention the deaths in childbirth or immediately after were only 3 per 1,000, whereas in the case of those who had no ante-natal attention the figures were 7 per 1,000. Taking 1927 by itself the figures were more remarkable. Among women who had ante-natal attention the mortality rate was 2.4 per 1,000, and among those who received no ante-natal attention it was 11.2 per 1,000. The ante-natal centres in Scotland were not numerous enough. In large towns like Glasgow and Edinburgh there were a certain number of such centres, but more were required, and they ought to be so situated as to be convenient of access to the women, who should not have to travel long distances. As a considerable period of waiting was in some cases inevitable, the centres should be made more comfortable. Some of the centres had not suitable conditions for the examination of women. The Department of Health ought to urge all local authorities which had ante-natal centres to see that they were such as would encourage women to attend. Strong pressure should be put on the local authorities which had no such centres at all. It was satisfactory, so far, that the figure for infantile mortality was down to 86, but the figure had always been higher in Scotland than in England, and this difference was due to the difference in housing conditions. The same steady progress was being made in regard to tuberculosis, but he would like to see it greater. That, again, was really a housing question. The country was spending a great deal of money on sanatoriums and on the treatment of tuberculosis, but the best medical authorities believed that with decent housing conditions they could sweep away the whole problem of tuberculosis in a generation. Little prominence had been given to the question of venereal diseases. They did not know whether they were decreasing or whether public health authorities were getting to the causes. There seemed to be an increase in gonorrhoea, although the evidence in regard to syphilis was that it seemed not to be increasing. They did not know whether the increase in gonorrhoea meant that more people were attending the clinics or whether it was an actual increase. This disease was so important and was costing local authorities and the country so much money that until they had some method for dealing with it, such as was suggested in the recent Edinburgh bill, they would continue to have inadequate results from a very large national expenditure. Continuing, Dr. Shiels said the report of the Scottish Department of Health brought out the fact that every four years, or about three times in the school life of a child, it was medically inspected. That was not enough. There should be a medical inspection of every child at least once a year. Certainly the medical staff would have to be increased. That would be a great economy, because if, in the course of school life, they could attend to the physical conditions of the children, they could turn them out at the end not only well educated, but physically well equipped. Attention should also be paid to systematic and daily exercises for children at school. They could honestly congratulate Dr. Elliot on the interest which he had taken in the experiment in regard to milk, and probably also for its initiation. The linking of two experiments, one in Scotland and the other as far off as East Africa, was of scientific interest and of great practical importance. The good work which Professor Leighton had done, and the interest he had taken in this subject for many years, in encouraging the milk producers of Scotland to supply pure and cleaner milk ought to be recognized. The present nomenclature of graded milk was misleading. People thought that Grade A milk was the best quality, whereas certified milk was the best. He would like information on the quality of the non-graded milk. Did the department take steps to obtain any samples of milk, and to subject them to bacteriological examination? The sale of tuberculous milk should be made a serious crime. The national health insurance scheme in Scotland was now well organized and working well. The report called attention to the fact that the action taken under the Economy Act, 1916, in reducing the State grant had prejudiced the possibility of extension of the dental and ophthalmic services. It was the duty of the Government to make the national health insurance system really comprehensive and to enable contributors to have at their command every medical and surgical aid. At present they were thrown back on the voluntary hospitals, which were overcrowded and had not enough beds. He echoed the hope expressed by Dr. Elliot in regard to the new hospital services under the Local Government Bill. That section of the bill would permit a development of municipal hospital service to supplement the voluntary service, and would make it possible for the ordinary citizen to obtain that specialist advice which was essential. The Labour party were sympathetic about research. There was, for example, the question of influenza, our knowledge of which was

limited. Research regarding that disease was badly needed. Measles and whooping-cough, though not seriously regarded by the public, were two of the most serious diseases, but they were not making a great deal of progress in regard to them. The entire sum which this wealthy country spent on research of all kinds was only about £20,000, and it would be a tremendous thing if, by research work, even a few hundred lives could be saved in Scotland each year. He wished to emphasize the importance of proper dental treatment for children. Most local authorities in Scotland had made such provision, but two of them—Argyllshire and Bute—had no provision at all. He appreciated Dr. Elliot's reference to the Highlands and Islands Fund. He (Dr. Shiels) had had an opportunity of seeing its work in Shetland and Orkney, and there was no question about its value and necessity. The Department of Health should put some pressure on local authorities in the North of Scotland who had failed to provide maternity and child welfare services.

Dr. ELLIOT, replying to the debate, said that the department were taking active steps to deal with maternal and infantile mortality. Their expenditure in the current year was 50 per cent. greater than the expenditure for which the Labour Government was responsible. With regard to milk tests, it was a question of quality, not of quantity. Last year 2,249 cattle affected by tuberculosis were slaughtered. The process of cleaning up the herds was continually going on and was bound to result in an improvement in public health. There was no increase in the number of school children suffering from malnutrition over last year.

The vote was agreed to.

Pensions Estimates.

On an estimate of £32,723,500 for salaries, expenses, and contributions of the Ministry of Pensions, which came before the House of Commons on May 8th, Major TRYON made a comprehensive review of the work of his department. He said the vote for the Ministry was still nearly the largest single vote in all the civil estimates. Payments from it affected the weekly budget of nearly one million families, and the beneficiaries of the Ministry numbered a million and a half. The total vote for the Ministry in the current year would amount to £53,723,500, and at the end of the current year the country would have spent in the fifteen years since the beginning of the war no less than £913,000,000 on war pensions, a sum roughly equal to the expenditure of both France and Germany together for similar purposes. Turning to the medical services of the Ministry, he remarked that the medical examination or boarding of pensioners for the assessment of their pensions was rapidly diminishing. The bulk of the work was now directed to the making of final awards. Only about 100,000 cases still drew pensions that were subject to further review. In a few months he hoped the Ministry would complete the medical boarding of all these cases for final award so far as they were likely to be found suitable. For many of the men it would probably be unfair in their own interests to give final awards, because they were cases actively deteriorating. The other side of the Ministry's medical work consisted of the medical and surgical treatment of cases. The demand for treatment of all kinds continued to decline at the same rate as during the last seven or eight years, and the hospital accommodation of the Ministry had been reduced proportionately. The Ministry, however, still maintained 17 hospitals of its own, with approximately 3,000 beds, and had a call on 25 other hospitals under the control of voluntary bodies which reserved the bulk of their accommodation for a further 2,000 cases. In addition, the Ministry used civil hospitals to a substantial extent, and on March 31 there were 5,601 patients in Ministry hospitals or civil hospitals. Explaining the system of final awards Major Tryon said that 6,000 cases had been given over and above their final award some further concessions under the system known as "correction of error," by which any officer or man who had received a final award and subsequently received hospital treatment could be given further pension if, at the end of his course of treatment, his condition was found to be seriously at variance with the degree of disablement which had been assumed for the purposes of final settlement. These cases were only about 1 per cent. of all the final awards made. The proposal that, in addition, any man who had received a final award should be given the further right to appeal at any time, and for an indefinite number of times, would make an end of final awards altogether.

Mr. F. O. ROBERTS, a former Minister of Pensions, called attention to a reduction of £290,000 in the provision of medical treatment under the Ministry of Pensions. He asked whether that saving could have been made if the men received the just treatment to which they were entitled, and whether too large a share of the responsibility for dealing with ex-service men was not now being left to private charities. He further asked whether the Ministry had devised any means of giving weight to the opinion of a claimant's own medical man when it was against the opinion expressed by the representatives of the Ministry. Had the Ministry considered the appointment of an independent medical tribunal to settle such questions? Medical representatives of the Ministry almost constantly disputed opinions which had been expressed by the medical advisers of claimants. Mr. Roberts cited the claim of a demobilized man for a pension on account of tuberculosis which had developed four months after demobilization, and which doctors of high standing had deemed to be due to the war, but which the Ministry had refused to consider, despite the prominence given to it by the British Legion. He pointed out that, although such benefit could be allowed to widows and orphans, only 71 grants had been authorized out of 494 applications, and he asked for an explanation of this grudging consideration. He further asked whether the Ministry of Pensions had considered widening the operations of village centres for the treatment of tuberculous patients. There now seemed justification for the conclusion that the proper way to deal with tuberculous ex-service men was to give them useful work in village centres. He also urged the provision of greater and wider occupational opportunities for neurasthenic ex-service men. He understood that from three to six days now passed before a man who had applied for treatment for any disability received a visit from the Ministry's medical officer. Could not some arrangement be made to avoid this delay, and might men not be attended by local doctors under products of award showing that their disability had been accepted by the Ministry of Pensions?

Sir BASIL PETO was glad to hear that 300 to 400 cases had been admitted for pension after the lapse of seven years from demobilization. There must be many more, he thought, which also deserved to be admitted after that limit, and he cited instances which had come to his knowledge.

Captain FRASER said it was probably true that war service left its mark upon every individual who suffered at all seriously, but not all of the 5,000,000 men who were recruited were subjected to hardships. If they gave to every man who had served a right of appeal for the rest of his life they would waste money on administration instead of spending it on pensions.

Sir FRANK MEYER said that if the House decided to do away with the time limit local voluntary boards would have to be set up, each consisting perhaps of a doctor, an ex-service man, a magistrate, and one or two other people of common sense and experience. Such a board would sift these cases, and only permit them to go to the Ministry if applicants showed there was a real connexion between their ailments and war service, and genuine reasons why the appeal should not be brought within the seven years' limit. He knew of cases where eight or nine years after the war men who had all that time suffered slightly from some wound finally found themselves worse and unable to carry on their job, having previously refrained from claiming pensions so as not to prejudice their chances in the labour market by appearing not to be wholly sound.

Sir MARTIN CONWAY cited two cases known to him of men who were gassed in the war, and who, fearing sentence of death of consumption were diagnosed, had not submitted themselves to medical examination until the seven years' limit had passed, when they were discovered to have consumption in a pronounced degree.

Dr. VERNON DAVIES congratulated the House on dealing with pensions from a non-party point of view. The question was not justice was being done to the ex-service men intimately concerned the medical profession because the skill and accuracy of diagnosis and of assessment by the medical profession decided whether an ex-service man could make out a case for a pension. Medical men had to remember to hold the scales of justice equal between the taxpayer and the ex-service man. Certain cases, such as the loss of an eye or a limb, could be recognized by everyone as being due to war injuries. A second class of case was definitely not due to war injuries, as, for instance, if an ex-service man developed small-pox or scarlet fever, and then claimed that it was due to his service. Medical men with experience were equally certain about some other cases were due to war injury or not. A man might say that he was perfectly right when he went to the war, but that after five or six years he developed a certain form of paralysis which he thought must be due to injury, shock, or nervous strain in the war. But medical men knew that form of paralysis was definitely the result of syphilis. The layman did not realize this, and thought that injustice had been done. A third class of case was doubtful even to the medical man. What was the right thing to do in this debatable ground? It was to see that the best, the highest, the best, and the most competent medical opinion before confirming an opinion. People had sometimes wondered whether the Ministry of Pensions had been as humane as it might be. He wished to testify to the kindness and humanity of Major Tryon, who had always received him with sympathy and done all he possibly could. He had seen him at work concerning a difficulty in the administration of the medical department. Major Tryon had offered him an interview with any of the medical staff, and had arranged for him to see the Director-General of Medical Services and his deputy. Dr. Davies then outlined the system whereby the medical officers of the Ministry dealt with assessments of claims, certificates of treatments. He explained that particular types of cases could be reconsidered in the Ministry by trained medical assessors, specially in certain diseases, such as tuberculosis and neurasthenia, and

if they desired anything to be explained when claimants came up for the award grant, the claims could be referred to another group of specialists. After a claim had passed through the area board, and had been considered by the awards branch in London, the House could safely say that every skill and medical attention had been given to it by expert medical men. The medical branch of the Ministry of Pensions was concerned solely with entitlement and assessment, and the financial aspect never came within their view. The medical men attached to the Ministry were absolutely fair and unbiased, and anxious to do the best they possibly could for the ex-service men. He cited two cases, one of a man who had venereal disease before the war, and another of a man who went to the war at about 50 years of age. The first developed symptoms of general paralysis of the insane a little sooner than might have been expected, and the second symptoms of arterio-sclerosis, followed by a stroke and paralysis. The Ministry accepted the first case as an aggravation due to war service, and the second case as absolutely due to war injury or war service, and not to the normal passage of time. Dr. Davies added that if the country got the idea that the medical profession as a whole was a profession of honourable men who were anxious to do all they could for the ex-service man, a better spirit would be created and suspicion would be reduced. Members must remember that in surgery and medicine one man might interpret a symptom in a certain way, and the next might, with equal honesty, interpret it in a different way. Very often the profession did not know which man was right until there was an operation or a post-mortem examination. When cases were referred to the Ministry accompanied by certificates from doctors, these certificates were given according to the best of the medical men's ability on the symptoms they had observed. But it was only fair to regard the opinions of experts on tuberculosis, neurasthenia, insanity, or wounds as of more value than that of the ordinary practitioner.

Mr. KELLY said he was prepared to accept the statement that the main body of doctors were honourable men, but he suggested that mistakes were made even by the experts and specialists. He was not sure that the House could rely in pensions matters on certificates handed out by medical men. A doctor might be able to say whether a man was suffering from a particular disease, but it was not the function of medical men to say whether a man was capable of doing his work From experience of many cases under the Workmen's Compensation Act Mr. Kelly judged that doctors' opinions were not worth a great deal. He remarked that most of the men now suffering from diseases after their return from the war had been passed as healthy before they went out, and it was difficult for the layman to believe that men who underwent hardships, such as having to sleep in the open without covering, would have been in their present position but for those hardships. He asked for special consideration for mental cases. Men who were mentally fit when accepted for war service had become unbalanced by the changed conditions under which they had to live at the front, and by the rush and scramble for jobs which they found when they came back to industrial life.

General CLIFTON BROWN drew the attention of the Ministry to two cases where constituents of his felt grievances. In one the constituent felt aggrieved because a pensions appeal tribunal had refused his application, and he had asked for the names of the two doctors who acted on the tribunal. The Ministry of Pensions had stated that to give the names was not its business, and the application was referred to the Lord Chancellor, who replied that the decision was in the hands of the president of the panel. General Clifton Brown thought the aggrieved man was justified in asking for the names, because he desired to set their opinions against the opinion of his own local doctor. The second case concerned an ex-officer with 100 per cent. disability, who occasionally suffered from neurasthenia and needed certain medical treatment immediately. His local doctor was not allowed to order at once the drug necessary in the case, but had to get permission from the Pensions Committee. They usually acceded to the request after a month or two, when the bad nervous attack had passed off. General Brown thought that the regulations might be administered so as to allow the local doctor who had had charge of the case for seven or eight years to act in the emergency.

Dr. FREMANTLE remarked that there was a definite decline in the provision made for surgical and medical cases in the Ministry's institution, and he asked what was the direction in which this was leading. The general surgical cases dealt with by the Ministry had decreased from 2,500 at the beginning of 1925 to something like half that number; in just over four years 64,000 surgical cases had been treated, and 60,000 medical cases, while there have been 26,000 neurological cases. The experience of neurological treatment thus gained had been of immense value to medical science, and for treatment in civil life hereafter. Naturally the decline in the number of cases demanded fewer institutions and smaller staffs. The institutions had been reduced from 250 in 1921 to 28; the hospitals from 75 to 20; the medical staff from 560 to 150; and the nursing staff from 1,300 to 360. He asked what steps were to be taken to ensure that this wonderful equipment and experience was to be properly used. As a service of this kind dwindled difficulty arose in giving the same proper treatment to those cases which still remained, while at the same time equipment, institutions, and services were lost which might otherwise be used for the general good of the community. The more they praised the organization and its great results the more anxious they must be to see that these results were not thrown away. He agreed with Dr. Davies that the medical men who were doing the difficult work of assessment were without fear and without reproach. But he had not the same absolute faith in the results of the judgements of their profession. All were liable to make mistakes, even when there might be two or three of them together, and his own experience was that when cases were brought before the Minister of Pensions in which there appeared to have been an error of judgement, even in the higher courts, medical men found themselves satisfied with the action taken. There must be protection for the public and there must be a limit. The fact that a man's disease was aggravated in some way by war service, and that he was worse off on that account, did not necessarily mean a corresponding liability on the State. He instanced a case of a farrier-sergeant who served in the war and died after seven years, when his widow applied for a pension. The question was whether the man's death from a tumour on the head was due to injuries received in the course of his duties during the war. It was shown that he was kicked on the head, but obviously a farrier expected to be kicked on the head from time to time. That was a case where a line must be drawn.

Captain FAIRFAX could not accept the contention of Dr. Davies that the value of the medical experts of the Ministry was necessarily and invariably greater than that of general practitioners. In some cases a man's general practitioner who had known his health for a long term of years was in a better position to diagnose his case than an expert who only saw him later on. Many laymen thought that if they went up and down Harley Street and Wimpole Street asking for a diagnosis of any complaint they would get a different diagnosis at almost every door, whereas if they relied on the common sense of general practitioners in provincial towns they would get a sound diagnosis and more uniform treatment. The specialist and the expert had become too predominant in the composition of the Ministry.

Replying to the debate, Major TRYON thanked members of all parties for the non-party way in which pensions had been treated, even on the eve of a General Election. Referring to a particular case raised by Mr. F. O. Roberts and the British Legion, Major Tryon said there was definite evidence with reference to the man's injuries at the time they had appeared, and this evidence could not be set aside by other medical evidence obtained eight or ten years later by men who had not seen and did not know the medical evidence in the possession of the Ministry. The House had decided that the final decision in such cases should rest with an independent tribunal whose decision was binding on the Ministry, and Mr. Roberts had failed through inadvertence to mention the fact that this case had been decided by such a tribunal. Members sometimes spoke as if to-day a seven years' limit absolutely barred all claims. That had been the position, but the present Government had arranged that where there was evidence claims could thereafter go through. There were 2,000 branches of the British Legion, but in the six months ending March, 1929, the Legion had only submitted thirty-seven claims to the headquarters of the Ministry. Major Tryon said he appreciated the references made to the medical services of the Ministry by Dr. Davies. He himself admired and respected their work, and resented attacks which were made, though not in the House, against the doctors of the Ministry of Pensions. The difficulty of the Ministry was generally not with the men who went to the front, but with the million men who enlisted, but were unfit to go to the front. An enormous proportion of the Ministry's medical men had been in the army and had served overseas. Of the whole staff 96 per cent. were ex-service men. Very often, of all the men concerned with the examination, consideration, and decision of the case, the only man who had not been at the front was the man applying for the money of the State on the grounds that he had been disabled by the war. Major Tryon thanked Dr. Fremantle for the interesting points he had raised about the inadvisability of losing the organization and experience now concentrated in Ministry of Pensions hospitals and staffs. In discussing that subject the House was handicapped because it concerned a large number of departments.

The House then agreed with the estimate for the Ministry, and the debate ended. The House also agreed without discussion to the estimates for other departments, including several votes for medical purposes, and to the report stage of a vote for £14,228,664 for the Ministry of Health. This included grants in connexion with public health services, and expenses of administration under the National Health Insurance Act.

The Mental Deficiency Report.

Mr. CHAMBERLAIN told Mr. Robert Morrison, on May 9th, that he had decided to publish the adult section of the Mental Deficiency Report, and that it would be issued as soon as possible.

Vaccination Statistics.

With the warning that the figures for expenditure and for vaccinations referred to different periods, and could not be strictly correlated, Mr. CHAMBERLAIN, on May 9th, furnished Mr. Broad with statistics of the cost to rates and taxes of vaccination in England and Wales in recent years, and of the number of persons vaccinated or revaccinated at the cost of the rates. The latter figures are as follows.

Year Ended September 30th.	Successful Primary Vaccinations.	Successful Revaccinations.	Total.
1923	415,549	316,641	732,190
1924	331,522	89,600	421,122
1925	270,755	40,939	311,694
1926	279,721	54,221	333,942
1927	305,005	113,117	418,122

Hygiene of Merchant Ships.

On the Appropriation Bill, in the House of Commons, on May 9th, Commander KENWORTHY opened a discussion on the mercantile marine. He said the statutory accommodation for a seaman was still 120 cubic feet, which was far less than for inmates of common lodging houses, prisons, or workhouses. Many shipowners had exceeded that allowance, and had provided very good accommodation. During the war the standard ships had the cubicle system in the forecastle, and it was much appreciated by the men. Now new ships were being built without the cubicle system. The President of the Board of Trade had few, if any, qualified medical men. If the health of the seamen was to be properly looked after the duty must be placed on the Minister of Health, who had the necessary medical officers.

Sir PHILIP CUNLIFFE-LISTER said the Board of Trade desired to bring the world into line with British standards. Then all countries could advance together. The regulations governing accommodation for seamen had been made as lately as 1923. At present the Board of Trade was collecting full reports of the conditions on different ships, and proposed to submit these to an interdepartmental committee of the Board of Trade and the Ministry of Health. The Board of Trade had no real complaints about the quality of food supplied to seamen. It hoped to get more detailed particulars on the rate of mortality due to sea service.

After some further discussion the subject dropped.

Artificial Cream.

The House of Commons considered, on May 9th, the Lords' amendments to the Reconstituted Cream Bill, the title of which had been altered in the House of Lords to the Artificial Cream Bill. Mr. A. V. ALEXANDER said the substitution of the word artificial was designed to create a bias in the mind of the public against the article known as reconstituted cream, and was quite unfair to the facts which were known to the Ministry of Health. Information had been communicated to the Ministry about the experiments which had been conducted by the London Hospital, and at a research laboratory in regard to reconstituted cream. These experiments showed that reconstituted cream was often more healthy for the public to consume than natural cream. A test made in a laboratory gave a bacterial count in matter of cream of 2,800,000 in a cubic centimetre compared with the very small count indeed in a sample of what was to be called artificial cream. These tests had also shown by proper research that in the making of reconstituted cream there was no destruction of essential by-products. The hospitals were using reconstituted cream, and the Ministry of Health was using it in its own buffet for the meals provided for the staff. He had had conversations with medical officers at the Ministry who believed reconstituted cream to be a thoroughly sound wholesome article. They would not prevent it being used in their own culinary department at the Ministry. Sir W. WAYLAND said Mr. Alexander might just as well argue from analysis made by hospital chemists that milk made from the soya bean, which analytically was exactly the same as ordinary cow's milk, and could not be detected from cow's milk, should be sold as ordinary milk. Farmers desired the article bought by the public to be real cream separated in the dairy, and not something called cream, which was made from butter, dried milk, and water, beaten up in a machine. The House of Commons then agreed to the Lords' amendment altering the title of the bill to the Artificial Cream Bill, and to other amendments, including one which required the registration of restaurants where artificial cream is sold, whether manufactured there or on other premises.

On the following day, as stated above, the bill received the Royal Assent.

Centres for Radium Treatment.—Mr. BLINDELL asked Mr. Chamberlain, on May 9th, what response he was sending to a resolution passed at the annual meeting of the British Hospitals Association recently held in London offering the advisory services of the association to the Ministry and the Radium Subcommittee as to the best and most convenient centres for radium treatment. Mr. CHAMBERLAIN replied that this resolution had not yet been formally submitted to him, but he proposed to bring its terms to the notice of the bodies through whom the new supply of radium will be administered as soon as they are set up.

National Health Insurance Fund.—Mr. CHAMBERLAIN, in a written answer, on May 10th, gave the approximate total receipts and payments of the National Health Insurance Fund in England and Wales during 1928 as £34,670,000 and £33,740,000 respectively. He added that the payments included about £810,000 for central administration.

Value of Skimmed Milk.—Sir JOHN GILMOUR, replying to Mr. Groves on May 7th, said that he was not aware that anything in the annual report of the Scottish Board of Health had created the impression that skimmed condensed milk should not be labelled "unfit for babies." There was no doubt that skimmed condensed milk was unsuitable for the feeding of infants, but food tests in Scotland had shown the value of good, fresh skimmed milk as a supplement to the diet of school children.

London Lock Hospital.—Answering Mr. Pethick-Lawrence and Captain T. J. O'Connor, on May 9th, Mr. CHAMBERLAIN said he understood a conference had been held that day between representatives of the governing body of the London Lock Hospital and of the former ladies' committee. The object of the conference was to reach agreement, both on proposals made by the board for the future management of the hospital and on the action to be taken with respect to certain former members of the staff. He could not tell the House of the results of the conference, but members would regard the board's action in seeking it as evidence of their desire to promote the harmonious and successful working of the hospital.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

As recorded elsewhere, Professor Henry Roy Dean, M.D., F.R.C.P., has been pre-elected by the Fellows of Trinity Hall to succeed Dr. Henry Bond in the Mastership of that College. Professor Dean received his medical education at the University of Oxford and St. Thomas's Hospital, and has held in succession the chairs of pathology at the Universities of Sheffield, Manchester, and Cambridge.

At a congregation held on May 12th the following medical degrees were conferred:

M.B., B.CHIR.—J. L. Franklin.
B.CHIR.—A. B. Connell, C. A. Francis.

UNIVERSITY OF LONDON.

THE annual Presentation Day ceremony took place at the Albert Hall on May 8th.

The Vice-Chancellor, Sir Gregory Foster, said that a message had been sent to the King and Queen expressing heartfelt joy at [illegible] King from his long illness. The King, in his [illegible] said that their Majesties realized the special [illegible] Presentation Day, marking, as it did under the revised constitution, a fresh era in the history of the University and the possession of the Bloomsbury site. The Vice-Chancellor gave a warm welcome to 3,383 men and women who had taken the degree of Bachelor during the year, as well as to 508 men and women who had graduated as Master or Doctor. He said that the vexed question of fuller facilities for the clinical education of women medical students, and the provision of more adequate hospital appointments open to women, was still unsolved. The question would be one of the first problems to be tackled by the new Senate and the Council that would shortly be constituted. Progress had been made towards the laying out of the Bloomsbury site, which was to be devoted mainly to the central activities of the University. To develop the site would require the generous co-operation of the City of London and of the friends of university education throughout the Empire, because the cost would not be far short of £2,000,000.

The Principal's report for the year 1928-29 recorded that the total admissions by all channels during the period was 9,708, as compared with 9,117 in 1927 and 3,852 in the last year before the war. The total number of candidates for all examinations was 34,940, against 33,903 in the previous year and 11,937 in 1913. The successful candidates at all examinations numbered 15,155, of whom 3,089 obtained degrees and diplomas. Reference is made to the appointment at St. Thomas's Hospital Medical School of Mr. S. J. Cowell to be the first holder of the Chair of Dietetics and to the appointment of Professor W. E. Le Gros Clark to the Chair of Anatomy. At Guy's Hospital Medical School Dr. [illegible] Donaldson has succeeded the late Professor Adrian Stokes in the Sir William Dunn Chair of Pathology, and the title of Professor

Morbid Anatomy has been conferred upon Dr. G. W. de P. Nicholson. The new Readership in Morbid Anatomy, tenable at Middlesex Hospital Medical School, has been filled by the appointment of Mr. S. L. Baker, and in view of the munificent gifts of Mr. S. A. Courtauld for the Institute of Biochemistry and the endowment of the Chair of Biochemistry at that school the title of the chair has been changed to the "Courtauld Chair of Biochemistry." At the London School of Medicine for Women Dr. Geoffrey Hadfield has succeeded Professor J. H. Dible in the Chair of Pathology. The title of Professor of Bacteriology has been conferred upon Mr. Alexander Fleming, in respect of the part-time post held by him at St. Mary's Hospital Medical School. At University College Hospital Medical School Dr. H. D. Wright now holds the new Readership in Bacteriology and Dr. C. R. Harington has received the title of Reader in Pathological Chemistry. Dr. Harold Raistrick has succeeded Dr. Percival Hartley in the Chair of Biochemistry at the London School of Hygiene and Tropical Medicine and Dr. Archibald Leitch now holds the title of Professor of Experimental Pathology at the Cancer Hospital. There had been instituted a Ph.D. degree in non-clinical subjects in the Faculty of Medicine and academic diplomas in clinical pathology and public health for internal students.

The special service was held at Westminster Abbey, when Bishop Gore preached, and the graduation dinner took place in the evening at Merchant Taylors' Hall.

Parliamentary Election.

The constituency of the University of London now comprises some 15,500 graduates who have registered as parliamentary voters. For the forthcoming General Election there are three candidates.

Dr. E. G. Graham Little, physician-in-charge of the Skin Department of St. Mary's Hospital, has been a member of the Senate since 1905; in 1924 he stood as an Independent candidate for the University seat, and was elected by a majority of 389 over the Conservative candidate; he is standing again as an Independent. The Liberal candidate is Mr. W. T. Layton, C.H., M.A., editor of the *Economist*, and formerly Director of the Economic and Financial Section of the League of Nations, who recently accompanied the Simon Commission to India. Sir John Gilbert, K.B.E., B.A., who has been adopted as the Conservative candidate by the University of London Conservative and Unionist Association, is a former Chairman of the London County Council, and has recently been elected for the sixth time as Chairman of its Education Committee; he was a member of the late Senate of the University, and has been elected to the University Court under the new Act.

Voting will be by post, and between the days of Monday, May 27th, to Friday, May 31st, both days inclusive.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary Council meeting of the Royal College of Surgeons of England was held on May 9th, when the President, Lord *Moynihan, was in the chair.*

Sir George H. Makins was presented with the honorary Gold Medal of the College, together with a document declaratory of its award, in appreciation of his valuable services to the College, more especially in arranging and describing the series of drawings in the Army Medical War Collection.

Diplomas of Membership were granted to 151 candidates. (The names were printed in the report of the comitia of the Royal College of Physicians of London, published in our issues of May 4th (p. 834) and May 11th (p. 888), with the exception of that of J. H. Boultbee.)

Mr. Charles Aubrey Pannett was elected a member of the Court of Examiners for the period of five years, and was admitted to the Court.

The following professors, nominated by the Canadian Medical Association, to act as Assessors to the Examiners at the Primary Examination for the Fellowship to be held at Toronto on August 6th, 7th, 9th, and 10th, for which there are 30 applications for admission, were appointed: *Anatomy*, J. P. McMurrich, M.A., Ph.D., LL.D., Professor of Anatomy, University of Toronto; *Physiology*, C. H. Best, M.A., M.B., D.Sc.Lond., Professor of Physiology, University of Toronto.

Sir Holburt J. Waring was appointed to go to Toronto as Visitor to the Primary Examination for the Fellowship to be held there in August.

The offer made by Mr. W. W. Ouless, R.A., to present to the College his portrait of Sir Arthur Keith was accepted with thanks.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.

A QUARTERLY meeting of the Royal College of Physicians of Edinburgh was held on May 7th, when the President, Dr. Robert A. Fleming, was in the chair.

Dr. Ella Ferrier Pringle and Dr. John Miller Woodburn Morison took their seats as Fellows of the College. Dr. Frederick William Woolrabe (Rhodesia), Lieut.-Colonel John Philip Cameron, C.I.E., I.M.S., Dr. Helen May Russell (Edinburgh), Major Ambuj Nath Bose, I.M.S., Dr. Andrew Rae Gilchrist (Edinburgh), Dr. Matthew Burn (Birmingham), and Dr. David Rutherford Dow (Fife) were elected Fellows.

The Parkin Prize was awarded to Dr. Harold Whitridge Davies, and the Freeland Barbour Fellowship to Dr. John Smith Fraser.

Obituary.

THE death of Dr. HAROLD SAUNDERSON SUGARS, D.S.O., M.C., which occurred at his residence, Carrigrenaud, Killiney, co. Dublin, on March 4th, as the result of war disabilities, will be deeply regretted by his many personal friends. He received his medical education in Dublin, where he graduated M.B., B.Ch., B.A.O. in 1908. He then joined the Colonial Medical Service, and was stationed in the Malay Peninsula. In 1915 he was released to join the R.A.M.C., and was attached to a battalion of the Yorkshire Light Infantry. He was awarded the M.C. in June, 1917, and this was followed by the D.S.O. for conspicuous gallantry and devotion to duty. "He showed magnificent disregard to personal safety in attending to the wounded under heavy fire for five days. On the fifth day his leg was broken, but this did not prevent him going through heavy shell fire to save the life of a corporal, whose main artery had been cut and who required immediate attention." He had to crawl part of the way, dragging his shattered limb over the ground as best he could. He reached the wounded man, who was under fire, and stopped the bleeding; both were then helped back to safety. The Arnott Memorial medal for bravery was also gained by him. A colleague writes: Dr. Sugars, or "*Hal,*" *as he was known to his friends, also excelled in* sport. He gained his cap at Trinity College, Dublin, in 1906, and was picked to represent Ireland as a Rugby international on several occasions. He played against New Zealand in 1906 and against South Africa in 1907. In the latter match he scored two of the three Irish tries. After the armistice he was appointed to the British Ministry of Pensions in Ireland, and became in due course Principal Officer in Ireland. His work here was characterized by the same devotion and strength of purpose as he had always shown. He leaves behind him in the Ministry a record of work done, deeply appreciated by his colleagues and the ex-service men. His early death has been widely felt as a real loss, and the sympathies of all go out to his widow and four children.

DR. JOSEPH WILLIAM DAWES, who died on April 18th at the age of 65, was one of the outstanding practitioners in North Staffordshire. He received his medical education at Edinburgh, where he graduated M.B., C.M. in 1885. Soon after this he joined his father in the practice founded by his grandfather at Longton. He succeeded to full control of the practice in 1894 and built up a very large connexion. He was honorary surgeon on the staff of the Longton Cottage Hospital for forty-six years; on his recent retirement his colleagues presented him with a silver salver, and he was elected consulting physician and trustee. He had held most of the available local offices in the British Medical Association, having been chairman of the North Staffordshire Division and president of the Staffordshire Branch; for some years he represented the Division at the Annual Representative Meeting. He also held the office of president of the North Staffordshire Medical Society, of which he was one of the founders in 1915; he was always a regular attender and a vigorous supporter. In public life he took great interest, and had been a justice of the peace for fifteen years; he was president of the local branch of the British Red Cross Society, and was instrumental in raising £6,000 during the war. Of late years he had been an ardent worker in connexion with the local branch of the League of Nations Union. Dr. George H. Sowry, president of the Staffordshire Branch, writes: Dr. Dawes never held back when asked to help any good cause. He was a very loyal Roman Catholic, and he not only gave freely in work and kind to his church, but its tenets entered into and influenced every act and thought in his life. In appearance he was very dignified, in manner always extremely courteous, and in his work he was devoted heart and soul to the interests of all his patients, whether rich or poor. He never spared himself nor missed the chance of doing a kind act. He died quite suddenly in the bedroom of a poor patient, and it is a great consolation to his family and friends to know that he passed away without

any bodily or mental suffering straight from the work he loved. He has left a widow, three sons, and two daughters. He was a great and good man, loved by everybody who knew him; he will be sadly missed.

Dr. THOMAS KIRKWOOD, who died on April 13th, received his medical education at Glasgow, where he graduated M.B., C.M. in 1892. He obtained the diplomas D.T.M.Liverpool in 1911, and D.P.H. Dublin in 1917. He held house appointments in Glasgow at the Royal Infirmary, the Maternity Hospital, and the Ophthalmic Institution; he was also house-surgeon to the Greenock Fever Hospital and assistant medical officer to the Govan Parochial Hospital and Asylum. He was for some time assistant medical officer at the Hereford County Council and City Asylum. He subsequently spent ten years in China, where he was in charge of a mission hospital containing fifty beds. During the war he held a commission in the Royal Army Medical Corps, and after the armistice acted as chairman of medical boards under the Ministry of Pensions for one year; he was then appointed a regional assessor in the South of Ireland, and carried on this work for three years. From January, 1925, to the end of his life he was medical officer to Dr. Barnardo's Homes. Dr. Kirkwood was a member of the British Medical Association. A colleague writes: 'One could not speak too highly of Dr. Kirkwood as a man and as a doctor. He had the highest possible aims in the discharge of his duty in the most practical and religious sense. A man of exceptional character and of the highest probity, he has done all through his working life everlasting good.

Dr. GABRIEL WILLIAM STAHEL FARMER, who died in Queensland, at the beginning of February, at the age of 64, was a son of the well-known composer and organist, John Farmer. He received his school education at Harrow, whence he entered University College, London, subsequently proceeding to Oxford. After studying medicine at the London Hospital he graduated M.B.Lond. in 1885, and M.B. Oxon. in 1890. He obtained the diplomas M.R.C.S., L.R.C.P. in the latter year, and the F.R.C.S. in 1894, and proceeded M.Ch. in 1895. He held appointments as house-physician and house-surgeon to the London Hospital, and senior resident medical officer to the Royal Free Hospital; he was then appointed lecturer and demonstrator of anatomy in Oxford, and, later, examiner in anatomy. He was awarded the Radcliffe Travelling Fellowship. In 1896 he commenced private practice in Oxford, and in 1898 was appointed surgeon to the Radcliffe Infirmary. Ten years later he travelled twice round the world, and then decided to start practice at Texas, in Queensland. In 1916 he removed to Maryborough in Queensland, where he resided until his death. He held the appointments of surgeon to the Lady Musgrave Hospital and honorary surgeon to the Maryborough General Hospital. Dr. Farmer was a member of the British Medical Association. He leaves a widow, and one brother and two sisters in England.

Dr. PERCY ROBERTS WILDE, who died on April 23rd at Bath, in his seventy-second year, came of a medical family, his father being in practice at Twyford, Hants. He was educated at Edinburgh and Aberdeen, and graduated M.B., C.M.Aberd. in 1880, proceeding M.D. in 1884. After holding clinical and teaching appointments in the University of Aberdeen he commenced practice in Bath over forty years ago. A man of striking personality with an original and independent mind, he was largely responsible for the foundation and progress of the Lansdowne Hospital, and was thus a pioneer in the establishment of the self-supporting hospital that depends entirely on the fees paid by its patients. He was also the founder and for many years editor of Wright's *Medical Annual*, and in its earliest days helped to nurse the little book, as it was then, into the portly volume that has for so long been familiar to readers all over the world. It will be remembered that he wrote several books on rheumatic disorders, on the etiology and treatment of which he had his own views. He leaves a widow, and one son and one daughter by his first wife, who died some years ago. One son was killed in the South African war, another went down in the *Indefatigable* at Jutland, and a third died about a year ago.

Medico-Legal.

THE SOCIETY OF APOTHECARIES AND AN UNQUALIFIED PRACTITIONER.

WE have received from the Clerk to the Apothecaries' Society the following communication:

> The officers of the Society of Apothecaries of London, having had the opportunity of investigating the alleged matters of complaint against Mr. Raphael Roche, have satisfied themselves that he had not contravened the provisions of the Apothecaries Act, 1815; and, having obtained from him the subjoined undertaking, the Society are glad to be able to announce that there is now no reason for invoking the powers vested in them under the aforesaid Act.

The undertaking, signed by Mr. Roche is in the following terms:

> "Following the recent correspondence between the Society and myself, terminating with my interview with your Clerk last week, I hereby undertake that I will not in the course of my work act in such a manner as to contravene the provisions of the Apothecaries Act, 1815, relating to acting and practising as an apothecary."

The Services.

THE GILBERT BLANE MEDAL.

THE Gilbert Blane medal, founded in memory of the late Sir Gilbert Blane and presented annually to the medical officer obtaining the highest aggregate marks at the examination for promotion to the rank of surgeon lieutenant commander, has this year been granted to Surgeon Lieutenant Commander T. N. D'Arcy, R.N.

TERRITORIAL DECORATION.

THE King has conferred the Territorial Decoration upon the following officers of the R.A.M.C.(T.F.): Lieut.-Colonel (Brevet Colonel) F. A. E. Crew, Edinburgh University Contingent, Senior Division, O.T.C., and Major H. G. L. Haynes.

DEATHS IN THE SERVICES.

Major General George William Robinson, C.B., Army Medical Service (ret.), died on March 14th, aged 75. He was born at Exeter on March 22nd, 1854, the son of the late George Robinson, Esq., of Sydenham Hill, and was educated at St. Thomas's, and after taking the M.R.C.S., the L.R.C.P.Lond., and the L.S.A., in 1876, entered the R.A.M.C. as surgeon on March 6th, 1880. He attained the rank of surgeon general on March 15th, 1911, and retired on March 22nd, 1914. He served in the Burma campaigns, with the Momeik column, in 1891, receiving the Indian frontier medal with a clasp, and in the Nile campaign of 1898, when he was present at the battle of Khartum, was mentioned in dispatches in the *London Gazette* of September 30th, 1898, specially promoted to lieutenant-colonel, and received the medal with a clasp and the Khedive's medal. The C.B. was conferred on him in 1911. He was unmarried.

Brevet Colonel Herbert Edward Deane, R.A.M.C. (ret.), died in London after a long illness on April 7th, aged 68. He was born at Hintlesham, Suffolk, on July 16th, 1860, the younger son of the late Rev. Henry Deane, M.A., rector of that parish, was educated at Middlesex Hospital, and took the M.R.C.S. and L.S.A. in 1881, also subsequently the M.D. Durham in 1905. Entering the R.A.M.C. as surgeon on July 29th, 1882, he became lieutenant-colonel after twenty years' service, and retired on October 8th, 1904. He served in the Tirah campaign on the North-West Frontier of India in 1897–98, and received the medal with two clasps. In 1899-1900 he was in charge of plague operations in Calcutta, for which he received the Kaisar-i-Hind gold medal. He rejoined for service on August 5th, 1914, the first day of the war, and was promoted to brevet colonel on June 3rd, 1917.

Lieut.-Colonel James McGann, R.A.M.C. (ret.), died on February 20th, aged 77. He was born at Carron, co. Clare, on July 28th, 1851, was educated in Dublin, and took the L.R.C.S.I. in 1872, and the L.K.Q.C.P.I. in 1873. Entering the army as surgeon on September 30th, 1874, he became surgeon lieutenant-colonel after twenty years' service, and retired on September 25th, 1895. When on the retired list he was employed in Dublin in 1904–7. He served in the first Boer war in 1881, in the campaign in the Transvaal, was present in the actions at Laings Nek and the Ingogo River, and was mentioned in dispatches in the *London Gazette* of March 10th and 29th, 1881. No medal was given for this campaign.

Medical News.

THE Home Secretary has appointed Dr. Herbert Morley Fletcher, senior physician to St. Bartholomew's Hospital, to be a member of the advisory committee on the administration of the Cruelty to Animals Act, 1876.

THE Prime Minister of the Commonwealth of Australia has, through the Secretary of State for the Dominions, requested the Minister of Health to liberate Dame Janet Campbell, the senior medical officer for maternity and child welfare at the Ministry of Health, to proceed to Australia in order to advise the Government on the organization and development of maternity and child welfare services for the benefit of the several States of the Commonwealth. In view of the special importance of these services in the interests of the Empire as a whole, the Minister has acceded to the request and has agreed to set Dame Janet Campbell free from her official duties in this country for a limited time.

THE next quarterly meeting of the Royal Medico-Psychological Association will be held on Wednesday, May 22nd, at University College, Gower Street, W.C., under the Presidency of Professor J. Shaw Bolton. The Maudsley Lecture will be delivered at 3.30 p.m., in the Botanical Theatre, by Professor C. Spearman, on "The psychiatric use of the methods and results of experimental psychology."

THE annual general meeting of the Fever Hospital Medical Service Group of the Society of Medical Officers of Health will be held at the House of the society, 1, Upper Montague Street, W.C.1, on Friday, May 24th, at 3 p.m., when officers and members of council will be elected for the session 1929–30. Afterwards there will be a discussion on "The uses of scarlet fever antitoxin," to be opened by Dr. W. Mair MacFarlane.

AT the next meeting of the Chelsea Clinical Society on Friday, May 24th, there will be a demonstration by Messrs. Kodak Ltd. of films of medical interest. The council of the society invites the attendance on this occasion of male practitioners who are non-members. Before the demonstration members will dine at the Rembrandt Hotel at 7.30 p.m. Further details may be had on application to Mr. Rugg-Gunn, 49, Harley Street, or Mr. Harwood, 90, Sloane Street, S.W.1.

AT the meeting of the Medico-Legal Society to be held at 11, Chandos Street, W.1, on Thursday, May 23rd, at 8.30 p.m., a discussion on acute arsenical poisoning will be opened by the president, Sir William Willcox, who will be followed by Professor Walker Hall, Dr. Roche Lynch, Dr. J. H. Ryffel, and Mr. Edward Hinks.

THE house and library of the Royal Society of Medicine will be closed to-day (Saturday, May 18th) and on Monday, May 20th. The next evening reception of the Society will take place on Wednesday, May 22nd, at 8.15 p.m. The Scott antarctic film will be shown in the Barnes Hall at 9 p.m.

THE thirtieth annual meeting of the Lebanon Hospital for Mental Diseases at Beirut, Syria, will be held at Friends House, Euston Road, N.W.1, on Tuesday, May 21st. The chair will be taken by Dr. R. Fortescue Fox at 5 p.m.

THE Fellowship of Medicine announces that on Tuesday, May 21st, Dr. L. S. T. Burrell will give the fifth lecture arranged for the M.R.C.P. course at the Medical Society of London, 11, Chandos Street, Cavendish Square, at 8.30 p.m.; his subject will be modern methods of diagnosis and treatment in pulmonary tuberculosis. The sixth lecture in the same course will be delivered by Dr. H. E. Archer, on tests of hepatic and pancreatic functions, on Friday, May 24th, at the same place and time. On Tuesday, May 21st, at 3 p.m., Dr. Alice King will give a clinical demonstration on chronic lung cases at the Queen's Hospital for Children, Hackney Road. On Wednesday, May 22nd, at 2 p.m., Mr. Swift Joly will demonstrate by operation at the St. Peter's Hospital for Stone, Henrietta Street. The second of the lecture-demonstrations by Dame Louise McIlroy will be given on Friday, May 24th, at 5 p.m., at the Royal Free Hospital. From May 27th to June 9th a comprehensive afternoon course for medical officers of welfare centres and others will be held at the Infants Hospital; visits will be made to other centres during the course. From June 3rd to 22nd the Royal Westminster Ophthalmic Hospital will provide an afternoon course consisting of clinical instruction and operations every day, with special classes on Mondays, Thursdays, and Fridays. Other courses next month will deal with gynaecology, at the Chelsea Hospital for Women, June 10th to 22nd; diseases of the chest, at the Victoria Park Hospital for Diseases of the Heart and Lungs, Cambridge Heath; proctology, June 24th to 29th, at St. Mark's Hospital; diseases of children, June 24th to July 6th, at the Children's Clinic and other hospitals; and an intensive course in medicine, surgery, and the specialties, at the Prince of Wales's General Hospital, Tottenham. All information regarding courses can be obtained from the Secretary of the Fellowship, 1, Wimpole Street, W.1.

THE committee of the British Red Cross Society's Clinic for the Treatment of Rheumatic Diseases, on the recommendation of the Medical Subcommittee, has made the following appointments to the honorary visiting medical staff of the clinic: Dr. M. B. Ray, Dr. F. D. Howitt, Dr. C. B. Heald, Dr. B. S. Nisse, and Dr. W. S. C. Copeman.

IN the list of medical candidates for the forthcoming General Election, printed in our issue of May 11th at page 876, the name of Dr. Betty Morgan was included in error. We understand that this candidate is not a member of the medical profession.

THE annual meeting and May dinner of the University of London Medical Graduates Society was held at the Langham Hotel on May 7th, with the president, Sir StClair Thomson, in the chair. Among those present were Sir J. Charlton Briscoe, Bt., Lady Barrett, C.H., Lady Briscoe, Mr. Herbert Tilley, Dr. Harry Campbell, Dr. Cole Marshall, Mr. W. McAdam Eccles (honorary treasurer), Miss Dorothy C. Hare, and Dr. C. A. H. Franklin (honorary secretaries). The president spoke of the growth of the society since it was formed last year, but pointed out, in view of the fact that the medical graduates of the University numbered over 4,000, that there was still plenty of scope for a very large increase in numbers, and he appealed to all members to bring in their friends and fellow graduates during the coming year. He remarked that the society had been formed at the right time, before the actual construction of the university centre in London, so that when that was established the society would already be in existence prepared to play its part in the development of the corporate spirit of the University. Sir StClair Thomson was re-elected president; Sir John Rose Bradford, P.R.C.P., Lord Moynihan, P.R.C.S., and Dame Mary Scharlieb were re-elected vice-presidents; and it was agreed to invite the following to serve as additional council: Dr. Rhoda Adamson, Mr. Victor Bonney, Dr. A. M. H. Gray, Dr. Louisa Hamilton, Sir Thomas Horder, Bt., and Mr. Harry Platt.

AT the recent annual meeting of the Society for Relief of Widows and Orphans of Medical Men Mr. V. Warren Low was elected president in succession to the late Dr. F. de Havilland Hall. The annual report of the society for 1928 showed that the invested funds amounted to £140,500, and the income therefrom £4,174 16s. In recording the deaths of two widows during the year attention is drawn to the fact that in the first case the husband had only paid £26 5s. in subscriptions and the widow had received from the society £2,040; in the second case £31 10s. had been paid in subscriptions and £990 had been received in grants by the widow. During the year £4,772 had been distributed in grants among fifty widows and seven orphans. The total membership of the society, which is both provident and benevolent, was 301 at the end of the year. Should a member die and leave his widow with an income not above £125 she would on the present scale receive a yearly grant of between £75 and £90, and any children under the age of 16 would receive a yearly grant of £60. Special grants may be made for orphans over the age of 16 to enable them to continue their education or start in some profession. The annual subscription for a member who at the time of his election is under 40 years of age is two guineas, if over 40 and under 50 three guineas, and over 50 four guineas. Membership is open to any registered medical practitioner who at the time of his election is resident within a twenty-mile radius of Charing Cross; he nevertheless remains a member should he move to outside the radius provided he conforms with the by-laws. The offices of the society are at 11, Chandos Street, W.1.

THE Minister of Health received a deputation, on May 8th, from the Women's Sanitary Inspectors and Health Visitors Association. The deputation was introduced by Dr. F. E. Fremantle, M.P., and included representatives of local [illegible] local government [illegible] ganizations. The [illegible] importance of the service rendered to the community by health visitors and other women public health officers. They urged that the time had arrived at which the salaries and conditions of service of these officers should be improved and standardized. The deputation was an outcome of a conference, held early in 1928, of representatives of local authorities and health visitors and other interested organizations, at which a resolution was passed calling for this reform. The Minister said, in reply, that the request made by the deputation had his entire sympathy, and he would give them all the help he could to persuade local authorities to offer such salaries and conditions as would attract the right type of woman to the service. The first step was to persuade local authorities and their representative associations of the need for improvement. He was, however, glad to know that conditions were

already to some extent becoming better, and he drew attention to the provisions of the Local Government Act, which require persons appointed as health visitors to be qualified in accordance with the Ministry's regulations. Finally, he suggested that it might be useful if a survey were made of the actual conditions of service in all parts of the country, and the deputation unanimously endorsed this proposal.

DR. D. E. FINDLAY of Gloucester has been made a justice of the peace for the city of Gloucester.

A REPORT on rural water supplies has been issued by the Ministry of Health; it urges the importance of devoting more attention to improving public wells, pumps, springs, and rain-water tanks in places where piped supplies cannot be installed. Recommendations are made with reference to the adequate storage of rain water, and it is added that local authorities require more powers than they at present possess, including the right to charge for water supplies provided by them. Although there has been substantial progress in recent years, there is still much to be done before conditions can be considered generally satisfactory.

THE April issue of the *Journal of the Association of American Medical Colleges* appears in two parts: the first includes a report on applications for matriculation in schools of medicine of the United States and the Dominion of Canada in 1928–29; notes on pre-medical education; on arts-medical courses; on four years' experience of the co-operative plan in medical education; on impressiveness in medical teaching; and on the status of functional pathology in the medical curriculum. The second part gives a list of fellowships and scholarships offered by the medical schools of the United States and Canada. This quarterly periodical is published at 25, East Washington Street, Chicago, at 2 dollars a year; single copies 75 cents.

THE fourth congress of French-speaking psychanalysts will be held in Paris under the presidency of Dr. A. Borel on June 3rd.

THE tenth annual international neurological congress will be held at La Salpêtrière, Paris, on June 4th and 5th, when the following subjects will be discussed: torsion spasms, introduced by Wimmer of Copenhagen; spasmodic torticollis, introduced by Barré of Strasbourg; and the surgery of the sympathetic, introduced by R. Leriche and R. Fontaine of Strasbourg. An address will also be delivered on malariotherapy by Professor Wagner-Jauregg of Vienna.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9861, 9862, 9863,* and *9864* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:
EDITOR of the *British Medical Journal, Aitiology Westcent, London.*
FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*
MEDICAL SECRETARY, *Mediocra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

SODIUM BARBITONE.

DR. F. P. STURM (Leigh, Lancs) writes: Can any reader tell me whether sodium barbitone remains stable in aqueous solution?

AFTER-EFFECTS OF "TWILIGHT SLEEP."

DR. FRANK E. KINGSTON (Leysin, Switzerland) writes: It would be interesting to know if the psychopathologists have anything to say on the subject of "twilight sleep." They assert, I believe, that some psychoneuroses may be traced to the deliberate forgetting of an unpleasant experience, which leads one to question whether the amnesia produced in a successful morphine-hyoscine narcosis is entirely free from undesirable after-effects.

AXILLARY HYPERIDROSIS.

DR. HESTER M. HENDERSON (Tunbridge Wells) writes: A severe case of axillary hyperidrosis was cleared up, after four or five doses, by a half-teaspoonful (ordinary breakfast spoon) of bicarbonate of soda in 2 oz. of water each night. When any slight return of the trouble comes (with extra exercise or hot weather), one dose keeps it down. A *cotton* vest with sleeves is worn next the skin, summer and winter; this can be boiled when washed. This very simple treatment has turned a miserable state into an easily controlled one. When the trouble is very severe a hot soda bath (handful of ordinary washing soda) distinctly helps.

INCOME TAX.

Appointment; Car Allowance.

"M. F. G. M." uses his own car for visiting various institutions under the control of the local authority for whom he acts. "The authority takes full responsibility for the maintenance of the car." In May, 1928, he sold his former car for £55 and bought his present car for £260. There is partial private use. Can he claim anything for depreciation?

*** If it is clear that the payments made by the authority do not include anything for the depreciation of the car there is no reason why a claim should not be made. We suggest that "M. F. G. M." should claim, for 1929–30, 20 per cent. of £260—that is, £52—as reduced by the proportion of private use. If he uses the car, as estimated on a mileage basis, three-quarters as to professional and one-quarter as to private purposes, his net allowance for 1929–30 would be £52−£13=£39.

LETTERS, NOTES, ETC.

PAROXYSMAL TACHYCARDIA.

DR. ROBERT A. WELSH (Felton, Northumberland) writes with reference to the note by Dr. W. F. Lloyd in the *Journal* of May 11th (p. 890): The term "paroxysmal tachycardia" was not used when I began medicine thirty years ago, but soon after commencing practice I had under my care a middle-aged man who suffered from such attacks; I did not know anything of its pathology, nor could I do anything for it, but he came in one day to tell me he had himself found a cure, which was exactly what Dr. Lloyd describes. This procedure always checked it, but he still got his attacks. I may say he had had acute rheumatism in early life, and died eventually of uraemia. I have only had one other case of this condition, and the patient, an elderly man, gets almost instant relief in the same way. "*Nullius-ed jam dictum, quid non dictum sit prius.*"

MATERNAL MORTALITY.

"Medical Investigator of Maternal Mortality and Medical Officer to Ante-natal Clinic" writes: I have read the paper of Sir Henry Simson on maternal mortality (May 11th, p. 879) with interest, and would draw attention to the details of the second case he cites. Would he support the compulsory internment in hospital of pregnant women found suffering from some abnormality? What means would he suggest for dealing with the mentality of the pregnant woman with regard to the medical advice she has received? Should the approved society refuse to pay maternity benefit in cases where this advice has been disregarded, thus rendering the woman poorer as well as sicker?

TITLES AND SUBJECTS.

SHORT headings are usually, but not always, best; now and then an author or an editor does well to ignore the adage about brevity and wit. A case in point is a note written by an operating room orderly, which appeared in the *Journal of the American Medical Association* for April 20th under the caption "Keeping the drawstrings on surgeons' operating trousers from sneaking back into the hem." This fulfils one of Samuel Butler's definitions: "A good title should aim at making what follows as far as possible superfluous to those who know anything of the subject."

MEDICAL GOLF.

THE Spring Knock-out Tournament of the Medical Golfing Society was won by Sir Kenneth Goadby, the runner-up being Mr. L. S. Plummer. The other semi-finalists were Dr. A. Hope Gosse and Dr. Ulysses Williams. The summer meeting of the society will be held on June 20th at Walton Heath, and the Canny Bowl Challenge Cup for mixed foursomes (with the Ladies' Medal) will be played for at Northwood on June 27th.

ASTHMA RESEARCH COUNCIL.

WE are informed by Surgeon Rear-Admiral T. T. Jeans, R.N. (ret.), that he has resigned his appointment with the Asthma Research Council.

IRON SUCCINATE.

WILL the contributor of a note on the use of iron succinate (mentioned on May 13th) be so good as to communicate his name and address?

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges and of vacant resident and other appointments at hospitals will be found at pages 44, 45, 46, 47, 50, 51, and 52 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 48 and 49.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 199.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

470. The Genesis of Heart Disease.

IN view of the existence of a family susceptibility to certain diseases such as tuberculosis, C. G. KERLEY (*Journ. Amer. Med. Assoc.*, February 16th, 1929, p. 517) suggests that there may be a type of child who is particularly susceptible to the infecting factors of morbus cordis. The patient with this inherently favourable soil for the development of infecting agencies is a child with potential heart disease. Such cases belong to one of three groups: those who have or have had rheumatic fever; or chorea; or those who complain repeatedly of pain in the extremities which cannot be accounted for by trauma or disease. Rheumatic endocarditis is responsible for more than 90 per cent. of the cases of juvenile heart disease, and months and perhaps years before morbus cordis develops children with potential heart disease show warning signals. Muscle pain and stiffness, sometimes joint pains, pain in the extremities by day and often by night, and restlessness during sleep, are ominous symptoms. The repeated complaint of tired legs is significant in a child who is apparently well; in such cases diseased foci should be eradicated, and Kerley asserts that the tonsils should immediately be removed whether they appear healthy or not. The teeth must be carefully examined and treated, and there should be competent inspection of the sinuses. In addition, predisposed patients should be given salicylic acid in some form, at first in sufficient amount to control the pain and discomfort, and later interruptedly for an indeterminate period; Kerley thinks it might be administered for five or ten days or more each month, and be continued for several months or even years. Its vigorous use should be resumed at the first indication of a return of the muscle pain or soreness. In the same way every patient with chorea should be regarded and treated as potentially having heart disease, being kept under medical supervision till the age of 12 or even later. Kerley considers that, when the dormant possibilities underlying "growing pains" are appreciated by physicians, the incidence of heart disease will be notably lessened.

471. Diagnosis of Mild Poliomyelitis.

E. FRIEDMAN (*New England Journ. of Med.*, February 21st, 1929, p. 384), who records two illustrative cases, maintains that every febrile disturbance in children, when accompanied by such symptoms as headache, stiff neck, spinal tenderness, and tenderness of the extremities, however mild these symptoms may be, should be looked upon with suspicion. Examination of the spinal fluid is of great help in doubtful cases, provided that the lumbar puncture is performed early and never later than the ninth day of disease, since the spinal fluid rapidly becomes normal again. The increased pressure returns to normal as soon as the febrile period ends. The globulin test is distinctly positive only in the first few weeks and then becomes doubtful. The sugar content of the spinal fluid varies but slightly on the different days of the disease. The average amount of sugar is 65 mg. per 100 c.cm., and is of importance in distinguishing poliomyelitis from tuberculous meningitis, which seldom has a sugar content of over 300 mg. per 100 c.cm. The cell count, which mainly consists of lymphocytes, is rather low in mild cases, averaging about 50 per c.mm., and rapidly returning to normal.

472. Chronic Pulmonary Infection.

L. H. COLLINS, jun., and K. KORNBLUM (*Arch. Int. Med.*, March, 1929, p. 351) record a clinical and radiological study of three cases of chronic pulmonary infection due to Friedländer's bacillus; they regard such a condition as a distinct entity which should be differentiated from other pulmonary infections. The onset in two of the cases was suggestive of broncho-pneumonia, and in the other of lobar pneumonia. The authors state that in some cases the condition can only be diagnosed from pulmonary tuberculosis by the results of bacteriological examination, the two conditions being in many respects so similar that the authors recommend that in cases of suspected tuberculosis in which tubercle bacilli cannot be discovered the sputum should be examined for Friedländer's bacillus. Extensive destruction in the involved areas of the lung leads to the formation of multiple abscesses and cavities, and causes a characteristic *x*-ray appearance only simulated occasionally by an influenzal pneumonia, in which the principal involvement is in the neighbourhood of the hilum. In the Friedländer type of pneumonia, however, the change is chiefly in the parenchyma of the lung. In the three cases reported the temperature fell by lysis, and the leucocyte count tended to be lower than that seen in an ordinary lobar pneumonia. An outstanding feature of this infection is the extreme indolence of the chest lesion, pathological changes being demonstrable by physical and *x*-ray examination several months after the acute infection has subsided.

473. Paraldehyde Poisoning.

P. SCHNEIDER (*Wien. klin. Woch.*, March 21st, 1929, p. 357) refers to the rarity, until recently, of cases of paraldehyde poisoning. The drug has, however, become popular owing to its rapid action and alleged harmlessness, and in spite of the inconvenience due to its fluidity, pungent odour, and peculiar burning taste. It has therefore been self-administered in numerous cases of suicide. According to the Austrian Pharmacopoeia the maximal single dose is 5 grams (80 minims), and the daily quantity administered should not exceed 10 grams. One author has reported a fatal dose of 15 to 20 grams (approximately 6 drachms); another has described the accidental poisoning of three female patients who were given in one dose 75 grams (approximately 2¾ ounces) of pure paraldehyde. They slept for from thirty to fifty hours, and on awakening appeared to be none the worse. In another case 30 grams (approximately one ounce) was administered without fatal result; on the other hand, a total quantity of 50 to 60 grams (2 ounces), taken during a period of thirty-six hours, has proved fatal. At the necropsy the gastric mucosa was found to be hardened, wrinkled, and greyish-white, resembling the condition found in phenol or mercuric chloride poisoning. Schneider records several cases of suicide by taking paraldehyde; in one case 4 grams (61¾ grains) of veronal and 50 c.cm. (nearly 2 ounces) of paraldehyde were taken. The post-mortem appearances were similar to those described above.

Surgery.

474. Gastric Ulcer and Tabes Dorsalis.

P. BONNET and P. DELORE (*Lyon Médical*, March 31st, 1929, p. 381) discuss the comparative frequency of gastric ulcer in cases of tabes dorsalis, and record the case of a man, aged 49, who had been admitted to hospital on several occasions in 1927 and 1928 for gastric crises. His sight had been failing since 1918, but the gastric crises did not begin until 1924. His pupils were unequal (the left being dilated), and optic atrophy was present. The Wassermann reaction was strongly positive in the blood and cerebro-spinal fluid, and he had all the symptoms of tabes dorsalis, except that the tendon reflexes were present and Romberg's sign was absent. The first attack lasted eight days, with vomiting, anorexia, and slight haematemesis; he received twelve injections of neosalvarsan. During the next three years he had only intermittent girdle pains and lightning pains in the lower limbs. In April, 1927, the second gastric crisis occurred, with agonizing pain, vomiting, and inability to retain fluid. This crisis subsided in five days under treatment. Vomiting, lasting three weeks, recurred a month later, and again after an interval of two months; this crisis lasted for seven days. In October, 1927, there was another crisis; the pain was so severe that it was relieved only by morphine, and vomiting was followed by slight haematemesis. A similar crisis, lasting six days, followed in February, 1928, and in August he returned with a still more severe attack, which lasted for three weeks, and was followed by two alarming haemorrhages. An exploratory operation disclosed an ulcer of the lesser curvature, in which a large eroded artery, occluded by endarteritis, was found. This was excised and gastro-mesocolostomy, by Murphy's button, was performed; there was no evidence of carcinoma. The attacks of vomiting became less frequent and the gastric crises ceased entirely; the patient's weight increased to 17 st., and he remains free from pain. Anti-syphilitic treatment has been given regularly. The authors have collected a number of similar records, occurring since two French authors described, in 1909, a fatal case of haematemesis due to a pyloric ulcer. Two German surgeons who performed vagus resection for relief of gastric crises found six cases of ulcer at ten operations. The present authors discuss the question of the connexion, if any, between gastric ulcer and tabes dorsalis; it has been suggested that these gastric ulcers are either syphilitic or trophic in

origin. They remark that the diagnosis is often difficult, and that the possibility of gastric ulcer must be considered in all tabetic patients who suffer from severe gastric crises, especially when haematemesis occurs.

475. Operative Treatment of Hepatogenous Jaundice.

P. FRANGENHEIM (*Zentralbl. f. Chir.*, April 6th, 1929, p. 854) states that 10 cases of icterus gravis with intact peripheral bile ducts on which he had operated within the last few years presented the following different histological appearances. There was central necrosis of the hepatic cells or subacute dystrophy of the liver in 6; intrahepatic cholangitis in 2; and in 2 cases intrahepatic peripheral infiltration was present without changes in the liver cells or bile ducts. The operative measures for hepatogenous jaundice are drainage of the hepatic duct, establishment of a biliary fistula, or the connexion of the gall-bladder or common bile duct with the stomach or intestine. Cholecystectomy or splenectomy is not required. The recovery rate of 41 cases collected by Schlegel on which operation was performed was 24 (58 per cent.). In 17 cases choledochostomy was employed. Frangenheim's statistics are better still, since 10 of his 11 patients recovered. As regards indications for operation, the author maintains that all cases of intrahepatic or hepatogenous jaundice which show a progressively unfavourable character should undergo operation. The earlier it is performed the more favourable the prospects of a disappearance of the hepatic changes and an escape of the flow of bile.

476. Contractures due to Burns.

S. L. KOCH and A. B. KANAVEL (*Journ. Amer. Med. Assoc.*, January 26th, 1929, p. 277), from an experience of seventy-seven patients with contractures following burns, advocate treatment with free full thickness grafts and pedunculated flaps; the grafts are employed when the essential loss involves the superficial tissues, and the flaps when it is necessary to cover important structures or to restore the normal contour. The free full thickness graft operation is completed in one stage, thus affording a minimum risk of infection and avoiding prolonged immobilization of the part. It is said to be of the greatest value in covering fresh raw surfaces over which firm pressure can be maintained—as, for example, on the hand, and the flexor surfaces of the wrist, elbow, and knee. After complete removal of the scar tissue, undermining the surrounding skin edges, and arresting the haemorrhage, a graft of the exact size and shape of the defect is separated (while tension is maintained upon it) from the underlying subcutaneous tissue of the abdomen or inner aspect of the thigh, and accurately attached over the raw surface with fine horsehair sutures. This is perforated in several places with a sharp-pointed scalpel in order to allow the escape of any serum, and the part is fixed in a position of complete extension, moderate pressure being maintained over the graft with clean moist sea sponges. The authors hold that the pedunculated flap should be used when important structures, such as tendons, nerves, vessels, or bones, are exposed in the floor of the wound, or in cases where subcutaneous tissue is needed to restore contour, as in burns of the face, and in which it is difficult to maintain prolonged pressure. As in the case of the full thickness graft, complete excision of the scar tissue and undermining of the edges of the defect are important; the flap is cut to the shape of the defect, but is one-third larger to allow for contractions. Only a thin layer of subcutaneous tissue is left attached to that portion of the flap which is to cover the raw surface, but sufficient subcutaneous tissue should be left attached to the pedicles to safeguard its blood supply. The authors found that both grafts and flaps tended to keep pace with the growth of the affected part, and that function and range of movement constantly increased, since the removal of the superficial restricting scars rendered progressive relaxation of the deep structures possible.

477. Dislocation of the Outer End of the Clavicle.

F. B. VALENTINI (*Il Policlinico*, Sez. Chir., March 15th, 1929, p. 117) remarks that the degree of dysfunction caused by dislocation of the outer end of the clavicle depends very much on whether the dislocation is complete or incomplete. He discusses the complete dislocations, and, after describing some of the more recent suggestions as regards their treatment, he reports a method which he tried with complete success in a recent case. The essential detail is the use of a thread of elastic to fix the parts and replace the broken ligaments; the elastic is boiled for fifteen minutes in a 2 per cent. carbolic solution. He illustrates the steps of the operation. The patient recovered complete functional use of the arm, and when seen more than a year later could move the limb freely in all directions.

Therapeutics.

478. Thallium Treatment of Ringworm.

V. PARDO-CASTELLO, J. J. MESTRE, and E. RIO (*Arch. Derm. and Syph.*, March, 1929, p. 409) record their experience in the treatment of tinea of the scalp in 32 children by the administration of the protoxide of thallium acetate given orally in one dose of from 7 to 8 mg. for each kilogram of body weight. All were cured except one in whom the disease recurred because of the early restoration of the hair before the infected hair had been completely eliminated. The authors conclude from experiments on animals that this drug acts through the endocrine system, as shown by the atrophy of the thyroid and suprarenals and by arrested growth; they add that it cannot be administered with safety to patients over the age of 14, since in adults it causes intense symptoms of endocrine dysfunction. No severe reaction occurred, though a few of the children showed slight symptoms of intolerance, such as diarrhoea, sialorrhoea, and leg pains. The authors believe that the drug produces a temporary arrest of the trophic action of the endocrine glands upon the growth of hair, and, while regarding it as comparing favourably with the use of x rays in epilation, they point out that, owing to its dangerous action upon the glands of internal secretion, its use in treatment should not be undertaken without full recognition of its limitations, possibilities, and contraindications. In their opinion x-ray depilation is the method of choice, in spite of the simplicity of thallium treatment, since it has yet to be determined whether the apparently temporary effects of the latter are followed by any permanent injury to the endocrine sympathetic system.

479. Potassium Sulphocyanate in Essential Hypertension.

R. C. LOGEFEIL (*Minnesota Med.*, March, 1929, p. 151), impressed by the results obtained at clinics in Germany in 1925 by the use of potassium or sodium sulphocyanate in the treatment of essential hypertension, or hyperpiesia, records his own experience in twenty-four cases treated with potassium sulphocyanate. The cases were mostly ambulatory, the blood pressure readings being taken with the patient in a sitting position, the first after resting for from five to ten minutes and a second from five to ten minutes later, the average from the two being regarded as the blood pressure for that day. All patients were placed on a moderately low protein and salt diet. One drachm of an 8 per cent. solution of potassium sulphocyanate in distilled water was given in a whole glass of water three times a day after meals; it was continued for a fortnight if no unfavourable symptoms, such as weakness, nervousness, or dermatitis, developed. At the end of a fortnight the drug was discontinued for two days and then started again, omitting two days in each week. After four weeks, or sooner according to the drop in pressure and general symptoms, the dose was reduced to twice a day, and on this basis was continued indefinitely, being omitted on two or three days each week as the case demanded. By this means accumulation was avoided, and in most cases the blood pressure was kept at a much lower level than it would have been without the drug. Renal and myocardial degeneration are said to be contraindications for its use. Logefeil regards potassium sulphocyanate as the most valuable drug known for reducing blood pressure, and claims that under proper precautions no unfavourable symptoms should result.

480. Plasmoquine in Malaria.

C. U. LEE (*National Med. Journ. of China*, February, 1929, p. 38) gives a report of the treatment of eight cases of malaria with plasmoquine, the synthetic product which is said to possess an antiparasitic action considerably greater than that of quinine. Its chief use is in its destructive action on the crescents in subtertian infections. Since quinine has little or no effect in removing the gametocytes of *Plasmodium falciparum* from the blood, and since the spread of the malignant form of malaria is due to the presence in the community of crescent carriers, it appears to Lee that plasmoquine might have a definite prophylactic value. The dosage advised for tertian and quartan malaria is 0·02 gram three to four times a day; administration is continued for four or five days after the temperature has become normal, and then for three days weekly for the subsequent four to six weeks. The disadvantage of its use has been the appearance of cyanosis, which is said to be due to the formation of methaemoglobin. Spleen puncture as a means of diagnosis is advocated in certain cases of malaria in which a prompt decision is desirable, and where repeated blood examinations fail to reveal the parasites. In certain cases this procedure was followed by febrile reactions and the appearance of parasites in the peripheral blood.

Radiology.

481. X-Ray Treatment of Prostatic Hypertrophy.

E. WOENCKHAUS (*Roentgen-Praxis*, March 15th, 1929, p. 89) reviews the literature, and records the results of *x*-ray treatment of fourteen cases of enlarged prostate at the Roentgen department of the Giessen Medical Clinic in the last two years. The ages of the patients ranged from 55 to 81, and the majority also suffered from other morbid processes, such as arterio-sclerosis, emphysema, spondylitis, obesity, and cardiac insufficiency. Although a diminution in size of the prostate could not be detected in any case, seven showed distinct improvement, but whether this was due to cure of a spasmodic condition or to a diminution of the hyperplasia which could not be detected clinically, or to a favourable effect on the chronic inflammatory process, could not be determined. The improvement was shown by a marked diminution of the amount of residual urine and complete disappearance of difficulty in micturition. In all the cases which were refractory to treatment the prostates were large and hard, and there was a considerable quantity of residual urine in the bladder; in two of the patients the condition was aggravated by *x*-ray treatment. Woenckhaus could only partially confirm the view expressed by several writers that it is chiefly the soft enlargements which are benefited by *x*-ray treatment. He found it impossible to say in advance whether it would be beneficial or not in a grave case of prostatic hypertrophy. Early cases, which offer the best chances of success, are likely to improve under other methods of treatment. Woenckhaus's conclusion, however, is that in early cases and in soft enlargements of the prostate without serious bladder complications *x*-ray treatment is a valuable, harmless, and conservative method which is often highly successful.

482. Lipiodol in Chest Diagnosis.

B. H. NICHOLS (*Radiology*, January, 1929, p. 1) considers that lipiodol introduced into the lungs is chiefly useful in the diagnosis of bronchiectasis and lung abscess; it is also of great value in the differentiation of lesions in the pleural cavity from lesions of the lung tissue. The outline of the trachea after the injection of iodized oil may aid in the definition of a mediastinal tumour or aneurysm. In pulmonary fistula the injection should be made under fluoroscopic control. The most important contraindications are: (1) hyperthyroidism or an idiosyncrasy to iodine; (2) advanced cardiac lesions; (3) pulmonary tuberculosis; except where considerable fibrosis has taken place; and (4) a marked elevation of temperature. The author favours the catheter method of injection under fluoroscopic observation for a large percentage of cases. He recommends the bronchoscopic method for haemorrhage without tuberculosis, the insufflation method for lesions at the hilus, and the transglottic route when dealing with cardiac cases. Injection through the cricothyroid membrane is stated to be the most desirable method in children. Whatever procedure is used care should be taken to avoid the entrance of much lipiodol into the gastro-intestinal tract, as dangerous absorption of the iodized oil may result.

483. Treatment of Rheumatic Carditis by X Rays.

R. L. LEVY and R. GOLDEN (*Amer. Heart Journ.*, December, 1928, p. 127) have treated 30 patients suffering from varying grades of rheumatic carditis with *x*-ray irradiations to the heart. Usually four applications, each representing 10 per cent. of an erythema dose, were given at fortnightly intervals; some patients received two or more such courses, a month's interval elapsing between each. The following alterations in the electro-cardiogram were observed: inversion or deepening of the T-waves in 18 cases; inversion or flattening of the P-wave in 9 cases; change in the electrical axis in 7 cases; occasionally alterations in the QRS complex; and extrasystoles and changes in the PR and RT intervals. Of the 30 patients, 21 showed clinical improvement at the end of the follow-up period. In some patients the improvement appeared to be definitely related to *x*-ray therapy, and it was found that early cases in the first attack of rheumatic fever were most likely to derive benefit. The five cases terminating fatally were all instances of progressive active rheumatism with severe lesions and consequent failure. It was observed also that 5 out of 7 patients complaining of severe chest pain were relieved by *x*-ray treatment. Orthodiagraphy showed no changes in the size or shape of the heart after irradiation, nor were there any evidences of unfavourable effects upon the course of the disease, although such symptoms as nausea, headache, and chest pain arose in several instances. Four patients suffering from subacute bacterial endocarditis were treated by this method, but in no case was there any improvement. The authors suggest that *x* rays act by desensitizing the tissues of the heart which have become allergic to certain toxins produced by the rheumatic virus. They also suggest that in a first attack of rheumatism *x*-ray therapy may minimize the danger of cardiac involvement.

484. Radio-diagnosis of Cerebral Tumours.

A. BÉCLÈRE (*Journ. de Radiol. et d'Électrol.*, December, 1928, p. 570) advocates simple radiography as the method of choice for diagnosing obscure cerebral conditions. Applied to the cranium, it differentiates such bony lesions as syphilitic osteitis of the inner table, acromegaly, changes due to marked intracranial hypertension, localized lesions caused by tumours adjacent to the meninges, enlargement of the internal auditory meatus or of the optic foramen in tumours of those nerves, and alterations in the sella turcica. Applied to the brain, evidence of displacement of the pineal gland, so frequently calcareous, would afford indirect proof of the presence, and perhaps the site, of a tumour. Meningiomas, gliomas, and suprasellar tumours of the pouch of Rathke, when sufficiently calcified, may be directly revealed. Other methods are the insufflation of the cerebral ventricles with air after withdrawal of all or part of their liquid contents (Dandy), and the introduction of lipiodol into the cerebral ventricles (Sicard), of sodium iodide into the cerebral arteries (Moniz), and of lipiodol into the cranial venous sinuses (Sicard). The last two methods are too recent for their value to be judged, but the former two have been well tried, and the air method is much to be preferred. In the brain the lipiodol method is not nearly so satisfactory as it is in the cord. Its introduction into the ventricles is painful, dangerous, and often uncertain. The insufflation method is not without danger and may terminate fatally. By it are revealed the form, position, and dimensions of the ventricles as altered by an adjoining tumour mass. The picture presented may be far from clear and its interpretation very difficult.

Obstetrics and Gynaecology.

485. Treatment of Vaginal Prolapse.

D. BISSELL (*Surg., Gynecol. and Obstet.*, April, 1929, p. 549) remarks that the term "fascia lapping," as applied to the tissues of the vaginal wall, is a misnomer. He shows, from a series of studies of the tissues removed at operations for all forms of vaginal prolapse, that the so-called fascia is not of that nature, or that, if it was originally a fascia, it has undergone some pathological change rendering it incapable of giving serviceable support in any reconstruction for such prolapse. It is pointed out that it is the vaginal musculature which constitutes the chief resisting tissue of the vagina, and that the normal vesico-vaginal septum derives its strength from the intimate union of the muscle tissues of the walls of the vagina and bladder. When it is necessary to correct a cystocele the anterior vaginal wall must be completely separated from the bladder, so that a fresh union can be established between the musculatures of their walls, and in order that the vaginal wall may be doubly strengthened by the lapping of its musculature. Bissell regards the etiology of cystocele as the loss of such complete and intimate muscle union of the walls of the bladder and vagina that each structure has to resist separately, and thus fails to maintain its normal position.

486. Parathyroid Treatment of Menorrhagia.

E. ALLEN and H. C. GOLDTHORPE (*Amer. Journ. Obstet. and Gynecol.*, March, 1929, p. 344) have been investigating the employment of parathyroid extract in excessive menstrual bleeding, with a view to making use of the increased coagulability of the blood which is encountered in hypercalcaemia. A series of fourteen young women were so treated; all had been subjected previously to the usual haemostatic remedies, such as oxytocics, injections of foreign proteins, and operations, but without benefit. Good results were obtained from parathyroid treatment in five patients, fair results in six, and poor results in three cases. The optimum daily dose seemed to be about 40 units, which was injected intramuscularly over a period of five days. A combination of this medication with the daily administration of 120 to 180 grains of calcium carbonate or calcium lactate by the mouth proved to be most effective; calcium levels bordering on the hypercalcaemic state were obtained only five times, and only by this combination. Patients in whom there was such a high blood calcium content usually complained of headache, nausea, and a rapid pulse, but the bleeding ceased. The authors believe that intravenous injections of the parathyroid extract are inadvisable; they remark that the same condition which causes the menorrhagia seems to predispose towards sterility. They add that a direct effect can be produced on

the endometrium by radium in patients where this medication fails, the ovaries being protected by the insertion of a lead screen.

487. Foetal Post-maturity.

C. HOLTERMANN (*Zentralbl. f. Gynäk.*, March 23rd, 1929, p. 711) defines protraction of pregnancy beyond term (foetal post-maturity) as the carrying on of gestation, in a person with a regular twenty-eight days' menstrual cycle, five or more days beyond the normal 280 days' period; further, he regards it as proved that death of the post-mature foetus frequently occurs before or during labour, and is almost inevitable when protraction of pregnancy is accompanied by abnormally large weight of the foetus. As a result of a series of six cases, seen within three months, of death of the post-mature child before or during labour (the weights ranged from 2,200 to 4,000 grams and term had been passed by from fourteen to sixty-two days), the attention of the Cologne Universitäts-Frauenklinik was directed to preventive measures in these cases, and the present article embodies the conclusions reached with regard to prophylaxis and treatment. Both are said to be dependent on regularly and frequently repeated auscultation of the foetal heart; death of the post-mature foetus is preceded by repeated attacks of arrhythmia, which may or may not be accompanied by bradycardia. Such attacks point to the necessity of accelerating delivery in the quickest and safest manner, but in protracted gestation prophylactic induction of labour by medical means will both obviate possible foetal danger and diminish the likelihood of operative intervention being required. Since the mortality of foetuses which have passed not more than ten days beyond normal term is little greater than that of normal vertex presentations (3.85 per cent., compared with 3.3 per cent. according to Frigyesi), induction of labour by medical means (hydrotherapy, administration of castor oil, and pituitary extracts) should be tried after five days' post-maturity. If this treatment, repeated, fails, recourse should be had to the rectal balloon, or even to vaginal intervention—by uterine bougie, for example. When cases of protracted gestation first come under observation after the tenth day or during labour, careful and frequent examination of the foetal heart should be made. Two attacks of arrhythmia, in cases in which previous pregnancies have resulted in death of the post-mature foetus, are said to justify immediate termination of pregnancy (preferably by abdominal Caesarean section), but in a primipara, aged 34, five arrhythmic phases were noted before hysterotomy was successfully performed. After ten days' gestation beyond term Caesarean section is advised if the presence of an abnormally large foetus is certain. Holtermann records three cases in which the life of the post-mature child appears to have been saved by Caesarean section, indicated by auscultation of the foetal heart, and one case of habitual protraction of gestation in which unavoidable postponement, for forty-five minutes, of Caesarean section (decided on by reason of foetal arrhythmia) led to loss of the child. With regard to the etiology of post-maturity in the foetus, it is noted that this is a condition which often recurs in successive pregnancies, and that characteristic alterations have been described in the placenta; these may be etiologically connected also with the attacks of foetal arrhythmia.

Pathology.

488. Significance of the Negative Phase during Vaccine Treatment.

G. RAMON (*C. R. Soc. de Biologie*, April 8th, 1929, p. 783) calls attention to the fact that if an animal which is being actively immunized with toxin is given a fresh injection of antigen a fall occurs in the antitoxin content of the serum. This phenomenon appears to be analogous to the so-called negative phase which is supposed to occur during vaccine treatment. The fall in the antitoxin content of the serum does not appear to be due to a simple combination of the antitoxin with the injected antigen, because there is no quantitative relationship between the two bodies. Working with horses undergoing immunization against diphtheria, the author found that the extent of the fall in antitoxin varied in different animals; that it was greater after the injection of toxin than of anatoxin; that it was appreciable only after large doses of antigen; and that even with large doses it did not exceed one-eighth of the previous titre. Seeking for the explanation of this phenomenon, the author noticed that horses injected with large amounts of antigen, particularly toxin, developed a local oedema, which contained about 4 or 5 litres of fluid. The oedema fluid had approximately the same antitoxin content as the serum. Since this fluid was pent up in the connective tissue, it is reasonable to argue that the blood volume must be brought back to its previous level by the absorption of water from the intestine; the dilution of the serum with this amount of fluid would cause a fall in the antitoxin titre. The author states that there was a correspondence between the fall in the titre of the serum and the extent of the oedema; as the oedema fluid was absorbed, the antitoxin titre of the serum gradually rose. He points out that after the intravenous injection of antigen there is a great congestion of certain organs, especially the liver, which may be doubled in volume. He considers, therefore, that the oedema after subcutaneous injection, or the intense congestion after intravenous inoculation, results in a local accumulation of fluid rich in antitoxin, and that the fall in the antitoxin titre of the serum is due to dilution with absorbed water. In favour of this explanation it was found that non-specific substances capable of causing oedema resulted in a similar fall in antitoxin. The author concludes that during the so-called negative phase there is no increase in the subject's susceptibility; his immunity is neither less nor more than immediately previous to the injection of the antigen.

489. Etiology of Infantile Choleraic Diarrhoea.

A. DUFOURT (*Journ. de Méd. de Lyon*," February 20th, 1929, p. 137) suggests that the most probable origin of summer diarrhoea is a thermostabile toxin contained in cows' milk. When diarrhoeic stools were filtered through paper and then through a Chamberland L 3 filter a dose of 2 to 5 c.cm. of the filtrate, injected into rabbits on alternate days, caused the death of the animals in from six to twelve days. The same result followed injections of the filtrate after it had been heated to 60° C. for two to twelve hours. When the filtrate was boiled for one minute the injections were better tolerated, but the animals still suffered from profuse diarrhoea. When, however, the filtrate was sterilized in an incubator at 120° C. for ten minutes the injections were much less noxious still. These experiments were repeated in goats with precisely similar results. Dufourt endeavoured to immunize the animals by injecting at first boiled filtrates, followed by filtrates heated to gradually diminishing temperatures. When the animals appeared to be doing well, sudden violent diarrhoea occurred occasionally. During the summer of 1927 Dufourt treated some children with immunized rabbit serum, but in 1928 he used goat serum. In fourteen cases recovery followed serum treatment. Five children died and two others were removed by their parents in a moribund state. Dufourt believes that these experiments prove that there are toxic products in the intestines of children suffering from choleraic diarrhoea which is not due to increased virulence or multiplication of intestinal saprophytic flora, except that in a few cases the virulence of *B. coli* appeared to be increased.

490. Cellular Division in Relation to Cancer.

E. MCDONALD (*Science*, February 15th, 1929, p. 175) remarks that, when unrestrained, the tendency of cells is to grow and multiply, and that the resting condition of adult tissue depends on the composition of the fluids surrounding it—that is, on its environment. Cancer is a disease characterized by division and multiplication of cells, and by more or less suppression of normal balanced cell activities with accentuation of cellular multiplication. Inhibition gives place to the embryonic characteristic of multiplication. In a normal cell four parts may be recognized: the alkaline nucleus (about *p*H 7.5); the acid protoplasm (about *p*H 6.6-6.8); the semi-permeable cell membrane; and the environmental liquid, which in the human body is the blood plasma and tissue juices with a normal *p*H of 7.36-7.38. Carrel and others have shown that cell division is dependent on environmental influences, and, because cancer is a disease of cell division, the study of the cancer-cell environment—that is, of the plasma—is of considerable importance. Since this cell differs so little from the normal cell, it is hopeless to expect to destroy it alone and not the surrounding normal cells also. Reding discovered that there was a low hydrogen-ion concentration of the serum in cancerous patients, together with a diminution in the ionized calcium and the total calcium content of the plasma. It has also been found that, after effective *x*-ray or radium treatment, the *p*H shifts to the alkaline side of the normal, and the ionized calcium is increased in amount; this treatment thus produces conditions in which cell division is hindered. McDonald suggests that by altering the environment of the cell (the blood plasma) such effects may be obtained as an aid to or a substitute for radiation in preventing cell division. Substances that may benefit in this disease will be those which restrain cell division without complete destruction of cell function, and those which will permit the cell to mature from its embryonic condition to that state where the inhibitions or restraint of the gradients are once more effective. H. O. NOLAN (*ibid.*, March 22nd, 1929, p. 330), commenting on McDonald's paper, attributes to Dr. Maude Menken the first discovery of the low hydrogen-ion concentration in the serum of cancerous patients.

HOWARDS'

Standard Ether

from Duty Free Rectified Spirit is now available

at the same price

as was formerly charged for that from Methylated Spirit

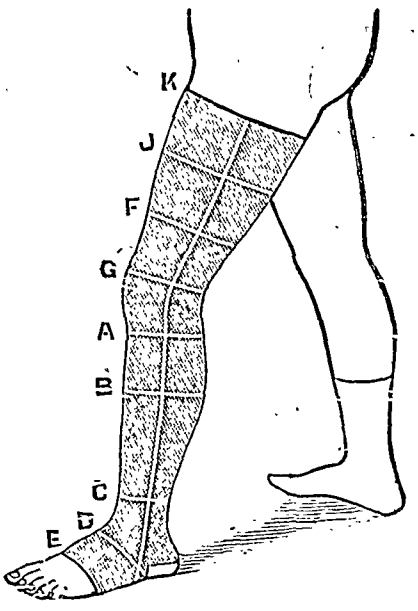
It is guaranteed that neither the Spirit which is used nor the Ether itself has at any stage been in contact with deleterious or dangerous impurities such as Wood Spirit, Pyridine, or similar denaturants, and is entirely free from peroxides, aldehydes and all other impurities.

HOWARDS & SONS, Ltd. (Est. 1797), ILFORD

W. H. BAILEY & SON

Elastic Stockings

Write for Catalogue.



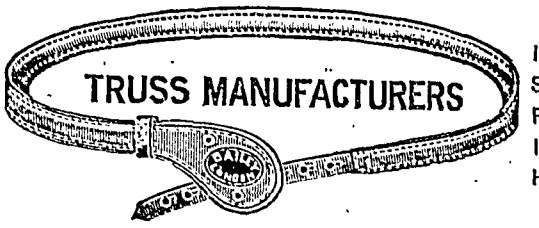
IMPORTANT NOTICE.

Messrs. W. H. BAILEY & SON are prepared to send (immediately on receipt of letter or telegram) thoroughly competent Assistants, Male or Female, to attend patients at their homes and to take Doctor's instructions. They personally superintend the making and fitting of the Appliance throughout, thus ensuring the best possible results.

Price Lists and Forms for Measurement Free.

TRUSSES

INDIVIDUAL ATTENTION GIVEN TO EACH CASE.

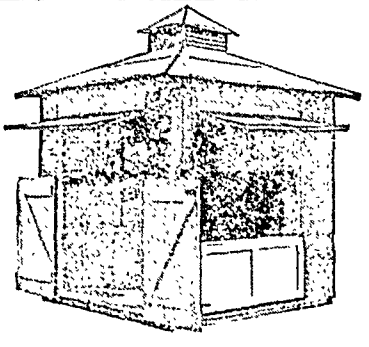


INGUINAL, SCROTAL, FEMORAL, & IRREDUCIBLE HERNIA.

MADE THROUGHOUT ON THE PREMISES. SPECIALS DISPATCHED IN 24 HOURS.
LOWEST PRICES WITH BEST QUALITY.

A COMPLETE REGISTER IS KEPT FOR ALL REPEAT ORDERS.

Telephone: GERRARD 3185. **45, Oxford Street, London, W.1.** Telegrams: BAYLEAF, LONDON.



OPEN-AIR SHELTERS

"PAPWORTH" & "COUNTY" SHELTERS

from **£12 : 10 : 0**

Write for illustrated folder to:

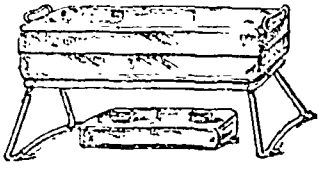
PAPWORTH INDUSTRIES, CAMBRIDGE.

SOLE MAKERS

ENHAM INDUSTRIES, ANDOVER.

SURGICAL INSTRUMENTS, FURNITURE, AND SUNDRIES.

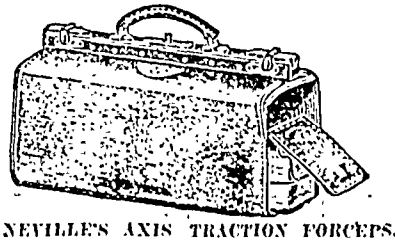
PORTABLE STERILIZER



INSIDE MEASUREMENTS. LENGTH 9½ INS. WIDTH 3½ INS. DEPTH 2½ INS.

NICKEL-PLATED ON COPPER, seamless boiler, complete with tray, folding stand, and 2-burner lamp. NEW 15/-, SOILED 12/6, SLIGHTLY USED 10/6.

MIDWIFERY "KITBAG" OUTFITS

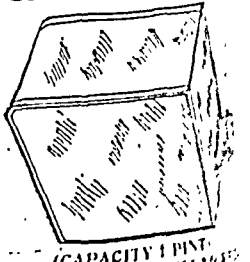


Comprising: MIDWIFERY KITBAG, solid cowhide, brown, size 16½ in. × 8 in. × 7 in., removable washable lining, with loops for bottles, etc.

STERILIZER FOR BAG, SEAMLESS BOILER, heavily nickel-plated on copper, with folding stand and lamp. Size 10 × 1 × 3½ in.

NEVILLE'S AXIS TRACTION FORCEPS, COLLIN'S PELVIMETER, SIM'S SPECULUM, PLAYFAIR'S PROBE, SCHIMMELBUSCH MASK, CHLOROFORM DROP BOTTLE, UTERINE FORCEPS, 5 BOTTLES, COMPLETE OUTFIT, **£8-8-0** (Carriage paid United Kingdom.)

SPIRIT CONTAINERS



(CAPACITY 1 PINT) SOLID COPPER, HEAVILY NICKEL-PLATED, with screw cap and lanyard, to prevent leakage. Size 5 × 3½ in. Wide mouth. OUR PRICE 13/- EACH (Postage 1/-)

INSPECTION CORDIALLY INVITED. NO OBLIGATION TO PURCHASE.

A. FLEMING & CO. (Dept. B.J.), 39, Victoria Street, LONDON, S.W.1. Tel.: Victoria [illegible]

SURGICAL SERVICE
SALTAIR

SALTAIR SURGICAL SERVICE

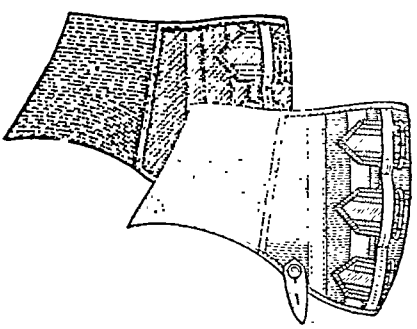
Guarantee

"We guarantee to alter, exchange, or accept the return of any appliance without cost, ordered by the Medical Profession, if not found suitable within fourteen days from date of supply."

Salt and Son Ltd.

Lighter clothing & lighter food for warm days

WHY NOT LIGHTER APPLIANCES?



The alternative wearing of two appliances—one for winter and one for summer—ensures hygiene economy and bodily comfort.

In the summer the winter appliance can be sent to us for repair, cleaning, and rehabilitation.

Medical Men are urged to point out to their patients the comfort and economy of such a method.

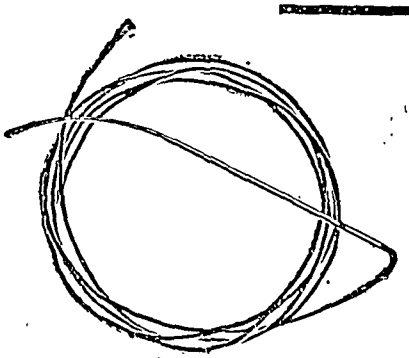
SALT AND SON LTD.
7, CHERRY ST., BIRMINGHAM.

ESTABLISHED 1793.

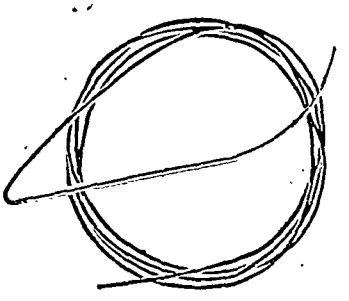
COPYRIGHT

London Eyeless Hospital Needles

Two New Models



Owing to repeated requests from surgeons for half-curved Eyeless Needles (Souttar Patent) these needles are now made as illustrated. They conform in all respects to the standard of the existing range of London Hospital Eyeless Needles



Half-curved round-bodied intestinal, with 3/0, 2/0, 0, 1 and 2 Catgut
4/6 per 3 tube box

Descriptive leaflet will be sent post free on application

THE HOLBORN SURGICAL INSTRUMENT CO., LTD., 26, THAVIES INN, HOLBORN CIRCUS, E.C.1

FOR DEAFNESS

Doctors prefer "ARDENTE" because

1. It is individually fitted to suit the case for young, middle-aged, or old.
2. It is simple and true-to-tone, and leaves the hands free.
3. It removes strain, thus relieving head noises.
4. It conveys sounds from all ranges and angles.
5. It is entirely different, uncopyable, and carries a guarantee and service system.
6. It is suitable for "hard of hearing" or acutely deaf.
7. It is helpful for conversation, music, wireless, home, office, public work, and sports.

"ARDENTE" STETHOSCOPE.
Mr. R. H. Dent makes a Stethoscope specially for members of the medical profession suffering from deafness. Many are in use, and excellent results are reported on the latest, which delighted Medical Men at the recent B.M.A. Meeting.

MEDICAL REPORTS.
Commended by all leading medical journals.—Mr. Dent will be happy to send full particulars and reprints on request.

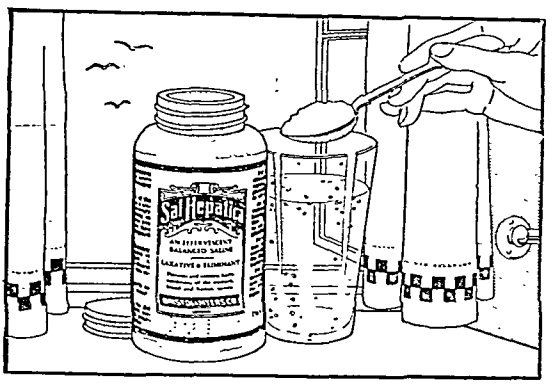
KEROL
CAPSULES



Relieves congestion of the gall bladder.

Elaborate menus, sedentary occupations and the consequent lack of exercise are largely responsible for the increase of cholecystitis. ¶ The daily exhibition of Sal Hepatica which ensures regular and complete evacuation is one of the most efficient antidotes to cholecystitis and its accompanying disorders. ¶ Sal Hepatica stimulates the flow of bile through the gall bladder and thus relieves hepatic congestion.

Sal Hepatica is not a 'patent medicine' nor is it advertised to the public.

Sal Hepatica

the proved medicinal saline laxative and cholagogue.

¶ Sal Hepatica contains sodium sulphate, sodium phosphate, sodium chloride and lithia citrate in an effervescent medium.

Samples for clinical trial will be forwarded on request to duly qualified members of the medical profession on application to

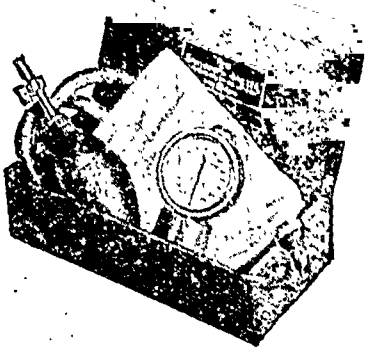
BRISTOL-MYERS COMPANY, 112, Cheapside, London, E.C.2

As Necessary as a Stethoscope

The present-day physician can ill afford to dispense with a sphygmomanometer as part of his visiting equipment. Many of the greatest medical minds of to-day advocate blood pressure tests as a guide to the eventual diagnosis.

The question of portability is easily solved by the S. & M. Portable type of Sphyg. as illustrated. This instrument—including Patent Arm Sleeve and Inflating Bulb with Control Valve—is contained in a leather carrying case 7 in. long, 4 in. wide by 3 in. deep.

Write for full details and prices.



Every genuine instrument bears the trade-mark "Tycos" engraved on the dial.

Obtainable from all reputable Instrument Dealers.

HARROGATE CORPORATION

F. J. C. BROOME,
General Manager of Wells and Baths.

The Royal Baths,
HARROGATE.
May, 1929.

Dear Sir,

An Invitation to Visit Harrogate

We are constantly advertising that Harrogate is a BRITISH Spa offering a "Cure" and a *Holiday unsurpassed at any* Foreign Resort, but unfortunately, advertising not being altogether free from exaggeration, our claims may leave you unconvinced.

To prove our point and to gain your goodwill for a BRITISH Spa we ask you to pay Harrogate a visit to satisfy yourself as to what we are doing and how we do it!

If you will send a postcard, a list of the concessions we ask you to accept during your stay, and Medical and "Lay" Literature, etc., will be sent you by return of post.

I am,
Yours truly,
F. J. C. BROOME,
Spa Manager.

MEDICAL CORRESPONDENCE COLLEGE

19, WELBECK ST., LONDON, W.1. Tel: Langham 1166.

PROVIDES HIGHLY SUCCESSFUL ORAL AND POSTAL COACHING FOR ALL MEDICAL EXAMINATIONS.

Special Preparations for all Surgical Qualifications.

F.R.C.S.ENGLAND. (Primary & Final.) CH.M.EDINBURGH. M.C.CANTAB.
F.R.C.S.EDINBURGH. M.S.LONDON.
And all other Surgical Degrees and Diplomas.

¶ The remarkable success of Students of the Medical Correspondence College at the higher Surgical Examinations is specially noteworthy.

¶ Both at the Primary and Final F.R.C.S. England the majority of our Students are successful at the first attempt, and Candidates who have failed at these Examinations on several previous occasions get through without difficulty after going through our courses.

¶ The Surgical Tutors of the College all hold either the M.S.Lond. or F.R.C.S.England, or both, and are highly experienced teachers.

¶ The Postal Courses are thoroughly clear, concise, and up to date, and the test questions are carefully selected from those set at previous Examinations, so as to embrace all parts of the subject. By working systematically through the Course the Student is brought up to the examination standard in the minimum time, and much unnecessary reading is saved.

VALUABLE BOOK

"How to Pass the F.R.C.S.," free on application to the Secretary.

Lady wishes to be Coached for ANATOMY and PHYSIOLOGY.—Write "E.D.," c/o CHARLES BARKER & SONS, LTD., 31, Budge Row, E.C.4.

Workmen's Compensation Act, 1925.

MEDICAL BOARD FOR SILICOSIS.

It has been arranged between the Home Office and the industries concerned that the periodic and other medical examinations required under the Refractories Industries (Silicosis) Scheme, 1925, and the Sandstone Industry (Silicosis) Scheme, 1929, shall be carried out by a joint Medical Board, the members of which will be allotted to certain centres, and which will have its central office at Sheffield. The Home Secretary proposes to nominate at once, in addition to the two whole-time Medical Officers already working under the Refractories Scheme, TWO MEDICAL PRACTITIONERS as Members of the Board.
The duties of the Medical Board, which are fully explained in the First Report of the Departmental Committee on Compensation for Silicosis, are to visit the different areas in which the Refractories and Sandstone Industries are carried on and to carry out jointly the periodic and other examinations and grant the necessary certificates under the two Schemes.
The scale of salary of the additional officers will be £750, rising by £25 a year to £900. The appointments will be for a definite term—not less than three years—and will be capable of renewal, but will be subject to termination at the discretion of the Secretary of State. Travelling expenses and subsistence allowances will be paid.
The salaries and expenses of the Medical Board are payable by the Refractories and Sandstone Industries Compensation Funds, but the Board work under Instructions issued by the Secretary of State and are directly responsible to him.
Further particulars and forms of application may be obtained from the Industrial Division, Home Office, Whitehall, S.W.1.
Applications should be made not later than May 31st.
Home Office,
Whitehall, S.W.1. May 7th, 1929.

Appointments worth about £100 p.a., and panel of 1,400. Fees from 2/6 to 21/-. Lowest midwifery 3 gns. Purchaser (if single) could reside in rooms, or suitable house obtainable. Premium 2 years' purchase.
16. SHEFFIELD.—Good-class non-panel non-dispensing PRACTICE in best residential district. Average income for last three years over £3,000. Fees 5/- to 21/-. Midwifery 3 to 10 gns.; about 30 cases yearly. Surgery premises can be rented on lease, and contain consulting room, waiting room, 3 bedrooms. Electric light. Garden. Purchaser can choose his own place of residence. Premium 1½ years' purchase, with 1 or 2 years' partnership introduction as required.
17. STAFFS.—LARGE TOWN.—Owing to ill health of present Incumbent, an old-established good-class non-panel non-dispensing PRACTICE is for immediate disposal. Income last year over £1,200. Fees 5/- to 10/-. Commodious house, in best residential road. Price for freehold £1,600, part on mortgage. Prem. £1,500, payable easy instalments.
18. SOUTH-WEST OF ENGLAND.—Large Thriving Hospital Town.—PARTNERSHIP.—The half or five-ninths share in an old-established better and middle-class non-panel general and surgical Practice can be acquired by a suitable gentleman possessing the F.R.C.S. degree. Receipts for the past three years average over £5,000 p.a. Good house, with ample accommodation, at present held on lease with option to purchase. Premium 2 years' purchase.
19. SOUTH-WESTERN COUNTY.—LARGE SEAPORT TOWN.—Old-established mixed-class PRACTICE averaging over £3,000 p.a., including panel of 2,100. Visits 3/6 to 10/6; midwifery (discouraged of late) 3 gns. upwards, about 30 cases yearly. Expenses light (Assistant not necessary). House contains professional accommodation, 3 sitting, 6 bedrooms, bathroom, etc. Large garden, garage. Vendor's freehold price £2,800, of which £1,200 can remain on mortgage, or might be rented at £96 p.a. Premium 1½ years' purchase, £3,000 down and balance by arrangement.
20. BORDERS OF NORFOLK AND SUFFOLK. — Very old-estab. good middle-class PRACTICE, averaging over £1,000 p.a., including panel of 530. Visits from 3/6. Easily worked. Very attractive house, modernized, and containing 3 reception, 6 bedrooms, bathroom (h. and c.), separate professional accommodation. Price for freehold £2,000. Premium £1,500.
21. BORDERS OF CORNWALL AND DEVON.—PARTNERSHIP.—A half share is offered in a very sound mixed-class Practice, situated in delightful district, near coast. Gross cash receipts upwards of £2,900, including panel of over 1,200, and good appts. Low expenses. Convenient house, with 3 reception, 4 bedrooms, and usual offices. Garden. Price £750, part on mortgage. Premium 2 years' purchase.
22. NORTH DEVON.—Within easy reach of favourite Town.—PARTNERSHIP.—A one-third share (to commence) in a well-established and increasing Practice, producing about £3,000 p.a., including panel of over 2,000. Fees 3/6 to 10/6. Choice of houses. Excellent sport, good schools. Premium 2 years' purchase, half down and balance by instalments.
23. LONDON, S.W.—PARTNERSHIP.—A one-fourth or one-third share in an old-established good middle and better working-class Practice, producing £2,500 p.a. Preliminary assistantship offered. Scotch Graduate, 25 to 35, preferred.
24. LONDON, S.W.—Pleasant Suburb.—Old-established PRACTICE, producing over £500 p.a., including panel of 417. Visits 3/6 to 5/-. Little midwifery. Eight-roomed house, with fair-sized garden. Rent £60. Premium £500.
25. WITHIN ONE HOUR OF LONDON (good train service).—Old-established mixed-class PRACTICE, offering good scope. Average income about £600. Fees 2/6 to 7/6. Not much midwifery. Easily worked. Semi-detached house in good condition, with 2 reception, 5 bedrooms, etc. Surgery and waiting room. Garden. Rent on lease £65 p.a. Premium 1½ years' purchase, or near offer.
26. GLOUCESTERSHIRE.—Very old-established unopposed Country PRACTICE, held by Vendor for the past ten years, and situated in attractive district, near good town. Cash receipts for 1928, £956, and this year at the rate of £700. Panel of over 500. Fees 2/6 to [illegible] house, with 6 bedrooms, etc. One acre of garden for freehold £1,200. Sport of all kinds.
27. CHANNEL ISLANDS.—Old-established general PRACTICE. Present income approximately £700, but large scope. Advice and medicine 3/6 to 10/6, visits and medicine 5/- to 15/-. Midwifery reduced. Commodious house, with 2 reception, 6 bedrooms, etc. Yearly tenancy freehold. Good schools. Price for practice and house £3,000.

Full Schedule of Terms and Conditions will be forwarded on application.

Printed and published by the British Medical Association, at their Office, Tavistock Square, in the Parish of St. Pancras, in the County of London.

$C_8 H_{10} N_4 O_2 + H_2 O$

THE injurious action of caffein, to which the ailing, recon-valescents and those in good health become liable by the habitual or excessive consumption of coffee and tea, is causing an increased interest in the medical world. There is already a comprehensive literature dealing with this subject; in many cases it absolutely bans the consumption of beverages containing caffein.

THE physician who is solicitous with regard to the welfare and ailments of his patients will specially value the knowledge that **H.A.G. COFFEE**—a caffein-free berry coffee—is obtainable, which in respect to aroma and palatableness, affords the same sense of enjoyment as ordinary coffee containing caffein, but without its harmful action on the cardiac, the nervous, and the vascular system.

WITH **H.A.G. COFFEE** the caffein is extracted from the unroasted coffee bean by a patented process, until only a slight, non-effective trace remains. Previous to this treatment, the coffee beans undergo a most thorough cleansing.

CAFFEIN-free **H. A. G. COFFEE** can confidently be recommended as the best and most valuable health coffee, and, in order to give members of the Medical Profession an opportunity of personally appreciating the hygienic characteristics of **H.A.G. COFFEE**, we shall be pleased to send a sample and literature free on request.

H.A.G. Coffee can be obtained in 2 sizes, price 3/2 and 1/8, either ground or in the bean. If your grocer has no stock we will supply post free upon receipt of your remittance

No. 3568. SATURDAY, MAY 25, 1929. Price 1/3

For Amylaceous Dyspepsia

PARKE, DAVIS & Co., introduced Taka-Diastase to the medical profession more than a quarter of a century ago, and it was not long before it came to be recognised as the standard remedy for so-called amylaceous dyspepsia.

Without question, Taka-Diastase is the most powerful of all amylolytic agents of vegetable origin. It is standardised to render soluble three hundred times its weight of dry starch in ten minutes, the starch being transformed to dextrins, maltose and dextrose.

Taka-Diastase is also an active proteolytic and, further, acts in neutral, slightly alkaline or slightly acid media. Whilst a very active therapeutic agent, Taka-Diastase is perfectly harmless. Being tasteless, it is freely taken by children and fastidious patients.

Taka-Diastase

Supplied as powder, tablets or liquid. Tablets are also available containing Taka-Diastase with pepsin, pancreatin or strychnine. It may also be obtained as an elixir, with bismuth, nux vomica and hydrocyanic acid. Further particulars will be sent to any member of the medical profession on request.

D PARKE, DAVIS & COMPANY 50 BEAK ST., LONDON, W.1.

Throughout the span

of allotted years — from infancy with restricted diet, through manhood with irregularity of habits, to old age with failing muscular strength and intestinal atony, constipation besets "all types and conditions of men."

The remedy lies not in the doubtful results of harsh cathartics, but in helping the colon back to normal activity.

AGAROL
BRAND
COMPOUND

The original agar-agar emulsion

is dependable, mild, non-irritating to the organs. It lubricates the intestinal tract, softens the impacted fæces, and reactivates the peristaltic force and action.

A liberal quantity of Agarol Brand Compound for trial sent without cost or obligation to physicians.

Agarol Brand Compound is the *original* Mineral Oil—Agar-Agar [illegible] pleasant taste without [illegible] flavouring; free from sugar, alkalies and alcohol; no oil leakage; no griping or pain; no nausea; not habit forming.

J. & A. CHURCHILL

SEVENTH EDITION. 2 Vols. 900 Illustrations (43 in Colour). 70s., postage 1s. 3d.

ROWLANDS & TURNER'S OPERATIONS OF SURGERY

"This is probably the most important modern text-book on Operative Surgery published by British Surgeons. "The volumes are not only safe as a book of reference, but of the greatest value to the general surgeon. The searching and detailed revision which has been carried out in the last edition does great credit to the ability and industry of the authors."—PRACTITIONER.

175 Illustrations. 16s., postage 9d.

PRACTICAL MIDWIFERY

By GIBBON FITZGIBBON, M.D., Late Master, Rotunda Hospital, Dublin.

"A book from the Master of the Rotunda Hospital, Dublin, can never be neglected, and a book on practical midwifery is likely to be particularly informing. An instructive book. . . . Stimulating and useful."—ST. BART.'S HOSP. JOUR.

FOURTH EDITION. 56 Coloured Plates and 309 Text-figures. 42s., postage 9d.

SEQUEIRA'S DISEASES OF THE SKIN

"Dr. Sequeira and his publishers are much to be congratulated on this, the latest edition of one of the best known text-books on dermatology. Without the least increase in bulk the work has been completely modernized, and contains in readable form all that can be regarded as proven in an expanding and increasing complex branch of medicine."—THE LANCET.

SECOND EDITION. 11 Illustrations. 12s. 6d., postage 6d.

A SYNOPSIS OF REGIONAL ANATOMY

By T. B. JOHNSTON, M.B., Ch.B., Professor of Anatomy, University of London, Guy's Hospital Med. School.

TWELFTH EDITION. 68 Illustrations. 28s., postage 9d.

GOODHART & STILL'S DISEASES OF CHILDREN

"The present edition will carry on for a further period the life and service of a British medical classic."—BRITISH MEDICAL JOURNAL.

THIRTEENTH EDITION. 1,063 pages. 48 Plates (8 coloured). 92 Text-figures. 28s., postage 1s.

TAYLOR & POULTON'S MEDICINE

Sections of Neurology by C. P. SYMONDS, M.D., and on Skin by H. W. BARBER, M.B., F.R.C.P.

"No text-book of medicine is quite so comprehensive as 'Taylor's,' and none deserves a greater popularity."—BIRM. MED. REVIEW.

By Prof. R. T. HEWLETT, King's College, London.

BACTERIOLOGY

EIGHTH EDITION. 38 Plates, 63 Text-figures. 18s. net, post. 9d.

PATHOLOGY General and Special

FIFTH EDITION. 48 Plates, 12 Text-figures. 18s. net, postage 9d.

PREVENTIVE MEDICINE

12 Charts, 5 diagrams. 18s. net, postage 9d.

5s., postage 3d.

THE PRINCIPLES OF PRACTICAL BACTERIOLOGY FOR SCIENTIFIC WORKERS

By J. H. JOHNSTON, M.Sc., and R. H. SIMPSON, M.D.

SECOND EDITION. 167 Illustrations. 21s., postage 9d.

MENNELL'S MASSAGE: ITS PRINCIPLES AND PRACTICE

"The book appears to us to be the best on the subject for the use of medical men."—BRITISH MEDICAL JOURNAL.

81 Illustrations. 21s., postage 9d.

PHYSICAL THERAPY IN DISEASES OF The EYE, EAR, NOSE, and THROAT

By A. R. HOLLENDER, M.D., Attending Otolaryngologist, American Hospital of Chicago; and M. H. COTTLE, M.D., Attending Otolaryngologist, Illinois Masonic Hospital at Chicago.

SECOND EDITION. With over 1,350 Illustrations. 21s, postage 9d.

A TEXT-BOOK OF BOTANY

FOR MEDICAL AND PHARMACEUTICAL STUDENTS.

By JAMES SMALL, D.Sc., Ph.C., F.L.S., F.R.S.E., Professor of Botany in Queen's University of Belfast.

SECOND REVISED EDITION. 273 Illustrations. 25s., postage 9d.

GWATHMEY'S ANÆSTHESIA

WITH COLLABORATORS ON SPECIAL SUBJECTS

SECOND EDITION. 8 Coloured Plates. 92 Illustrations. 18s., postage 9d.

MOORE'S MEDICAL OPHTHALMOLOGY

"As a connecting link between the specialized science of ophthalmology and the wider scope of general medicine, it is unsurpassed in our literature for its conciseness and clarity and its wealth of detail."—BRITISH MEDICAL JOURNAL.

2 Plates and 123 Text-figures. 15s., postage 7d.

WOOD JONES' PRINCIPLES OF ANATOMY AS SEEN IN THE HAND

"One of the most notable contributions ever made to the literature of British anatomy . . . places the author in the first rank of British anatomists."—BRITISH MEDICAL JOURNAL.

117 Illustrations. 30s., postage 9d.

JACKSON'S EFFECTS OF INANITION AND MALNUTRITION UPON GROWTH AND STRUCTURE

By C. M. JACKSON, M.S., M.D., LL.D., Professor of Anatomy, University of Minnesota.

THIRD EDITION. 59 Illustrations. 25s., postage 9d.

EXAMINATION OF WATERS AND WATER SUPPLIES

By J. C. THRESH, M.D., and J. F. BEALE, M.R.C.S., L.R.C.P., D.P.H.

"The book is a work of sheer merit. The more it is consulted the greater is the appreciation of the whole-hearted work the authors have done."—THE ANALYST.

DISTINCTION ALWAYS MERITS ATTENTION

The Ascot Six

The car of distinction and merit.

Designed and constructed for the requirements of the owner driver.

How often one hears the expression—cars are built for the care and attention of mechanics only. We refute that statement when applied to THE ASCOT "SIX."

Special care and attention has been given to accessibility, ease of control, reliability, with a minimum of required attention and a low cost of maintenance and upkeep.

The MOTOR TRADER says: "The chassis shows simplicity carried, surely, to the limit."

Before you purchase your new car, may we demonstrate THE ASCOT "SIX" to you, either through your local Agent or with us direct.

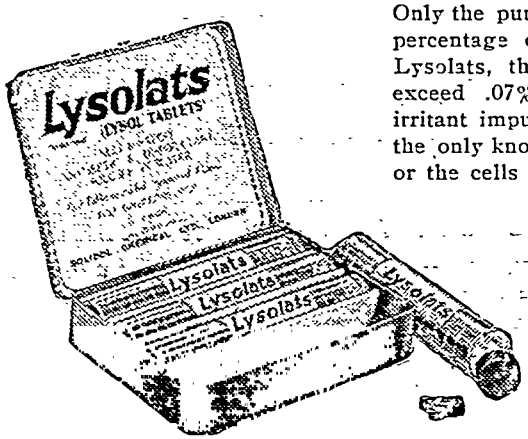
The Solid Form of Lysol contains the Highest Grade of Cresylic Acid

Members of the Medical Profession are invited to write for free samples of Lysolats to Solidol Chemical Ltd., Ashmead House, Disney St., London, S.E.1

In emphasising the care necessary in the choice of a lysol, the makers of Lysolats are repeating a warning that has been made time and again by medical men. The cresylic acid used in the cheap liquid lysols is often deficient in Meta-Cresol, which, as doctors know, is the most actively bactericidal of the isomers.

Only the purest grades of cresylic acid containing a high percentage of Meta-Cresol are used in the making of Lysolats, the solid form of lysol. Impurities do not exceed .07%, including water. The absence of these irritant impurities is one of the reasons why Lysolat is the only known antiseptic that is non-toxic to the plasma or the cells of the human tissue.



Lysolats
PATENT 118667 (LYSOL TABLETS)

Lysolats are packed in handy tins containing 40 and 80 tablets (at 1/3 and 2/- respectively), and also in tins of 1,000 tablets.

Famous as The Food of Royal Infants

also for invalids, the aged, and all persons of weak digestion

ROBB'S NURSERY BISCUITS have no equal. Easy of assimilation, a nourishing and sustaining diet, its appetising flavour is greatly appreciated by both young and old. Very welcome as a substitute for the ordinary bread-and-milk diet. Can also be lightly baked, with eggs and milk, to supply a delicious custard pudding.

Robb's NURSERY BISCUITS

Highly recommended by eminent Accoucheurs and Physicians throughout the world as the most reliable food for Infants over six or seven months.

ROBB'S NURSERY BISCUIT POWDER is recommended when a feeding bottle is to be used, also as a diet for invalids.

ROBB'S DIGESTIVE RUSKS, TOPS and BOTTOMS, GINGER NUTS, and CHARCOAL BISCUITS are specially recommended for invalids and convalescents.

Send for large free sample and descriptive booklet, etc.

Alex. Robb & Co Ltd. (Dept. 6), NURSERY BISCUIT FACTORY, ATKINS ROAD, CLAPHAM PARK, LONDON, S.W.12.

Prescribed in numerous cases *of nervous and heart disorders, also rheumatic conditions, etc.*

The active substances of the extracts from cone-bearing pine trees (Pinus silvestris, Abies alba, Pinus montana) is found in an oily substance commonly known as pine oil.

Novopine Sparkling Pine Bath Tablets contain this oil in a convenient form and an effervescence is introduced to facilitate successful solution in the bath. Their therapeutic value lies in their action on skin, lungs, and heart. For, in addition to the direct action through the pores of the skin, the ozonic aroma given off is automatically inhaled during the taking of a hot bath.

Besides their general cleansing and health-giving properties, they have been found especially beneficial as a remedy against nervous heart diseases and kindred disorders

Samples on request from Natural Products Ltd., 40, Furnival Street, E.C.4.

ACRIFLAVINE
"B. D." Brand

Ample proof of the value of Acriflavine "B. D." Brand as a wound antiseptic was afforded during the war. Subsequently it was shown to be an antiseptic of wide application for a variety of conditions.

Acriflavine "B. D." Brand is non-toxic in spite of its powerful antiseptic action; moreover, it possesses the unique advantage of an augmented bactericidal activity in the presence of serum.

In the irrigation treatment of gonorrhœa Acriflavine has been described as being more suitable than any other antiseptic, whilst in cases of uncomplicated B. coli infection Acriflavine treatment has been employed with success.

Acriflavine "B. D." Brand is issued in the form of a crystalline powder, also in tablet form, in concentrated solution and in 1 in 1,000 solution ready for use either as a lotion or for injection, in any of which forms it can be obtained from the principal pharmacists.

The best results are assured when the "B. D." Brand is specified

Invaluable as a Galactagogue

This nourishing and sustaining food drink is helpful to nursing or expectant mothers

NOT only hundreds, but literally thousands of cases are recorded in which this well-known preparation — Horlick's Malted Milk — has proved its efficiency as a body-building food.

It is particularly valuable as an addition to the diet of the expectant and nursing mother. For Horlick's is a perfectly balanced food containing fat, proteins and soluble carbohydrates combined together in correct nutritive ratio. It is prepared from fresh, full-cream cows' milk, selected wheat and malted barley — and, during manufacture, is partially predigested to ensure easy assimilation.

Horlick's is rich in valuable malt-sugars, but contains neither cane sugar nor free starch. It is therefore extremely easily digested, and highly productive of energy.

These characteristics make it valuable as a galactagogue. Its abundant nutriment supplements any deficiencies in the mother's regular diet, and promotes a regular and nourishing supply of milk, and its easy digestibility makes it acceptable when other forms of nourishment are unwelcome.

Taken during pregnancy, it builds up the mother and helps to maintain her vitality. A cupful taken regularly first thing in the morning frequently abolishes and almost invariably alleviates the discomfort of morning sickness.

Horlick's is now obtainable in two forms — the original, natural-flavoured Malted Milk, and the new Chocolate Flavoured form — identical in its constituents with the original Horlick's, but flavoured with fine chocolate. Horlick's is sold in sealed glass bottles, price 2/-, 3/6, 8/6, 15/-. Also in tablet form.

Further details may be obtained from Horlick's Malted Milk Co., Ltd., Slough, Bucks.

ALOCOL

Colloidal Hydroxide of Aluminium

THE increasing prevalence of gastric ulcer and hyperchlorhydria has produced an advance in the treatment of these diseases.

"Alocol" (Colloidal Hydroxide of Aluminium) provides an antacid medicament far superior to subnitrate of bismuth, bicarbonate of soda and other alkalis. These merely afford a certain degree of ease, without bringing about a permanent relief of the condition.

"Alocol" absorbs the excess of hydrochloric acid without interfering with the normal antiputrefactive function of the gastric juice or harmfully affecting the processes of nutrition.

"Alocol" has been subject to extensive clinical trial, and literature giving full particulars of the results will be gladly sent to medical men on request.

For Acute or Chronic Cases of Hyperacidosis

For Gastric Duodenal or Pyloric Ulcers

FRANK COOPER'S OXFORD MARMALADE

By Appointment. *By Appointment.*

A One-pound Jar of Cooper's "Oxford" Marmalade will be sent free to any medical practitioner on request.

FRANK COOPER LTD.
Victoria Works,
OXFORD.

The Certificate of the International Institute of Physiology and Hygiene states:

"This marmalade is prepared from the highly esteemed Seville orange and pure sugar. It represents a table commodity of the highest possible dietetic value and scientific skill in manufacture. It is entirely free from added colouring or flavouring bodies, and contains no injurious preservative material. It presents the delicate and slightly bitter flavour so much appreciated in home-made marmalade, and possesses stimulating and gustatory properties of a high order. The use of such marmalade as the kind under consideration is highly beneficial, for it promotes a healthy appetite and a natural flow of the digestive juices, and acts generally as a tonic to the stomach and liver."

INSULIN "A.B."

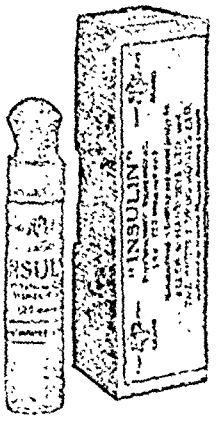
TRADE A B MARK **Brand**

"A.B." Insulin was the first British Insulin available for use by the Medical Profession and after almost five years retains its reputation as the Insulin which can be relied on to give consistently satisfactory results. The supremacy of "A.B." Insulin is due entirely to the stringently high standards of purity, therapeutic efficiency and stability self-imposed by its manufacturers.

"A.B." Insulin connotes:

Uniformity of unitage.
Full potency and stability in all climates.
Purity and complete sterility.
Absence of reaction-producing proteins with consequent noteworthy freedom from unpleasant by-effects.

The activity of "A.B." Insulin is guaranteed by the most complete physiological tests and standardisation on the basis of the accepted unit. Before issue, each batch is passed under the authority of the Medical Research Council.



Supplied in two strengths:

20 units per c.c.

Prescribe 'Mistol' for the Nose and Throat.

MISTOL has proven especially efficacious in coughs and colds, simple, congestive, and catarrhal rhinitis, hoarseness, bronchitis, and laryngitis.

Mistol consists of menthol, eucalyptol, camphor, and chlorbutynol carefully combined in proportions recommended by leading nose and throat specialists. A specially prepared petroleum base keeps the soothing, healing ingredients in direct contact with the mucous membrane for a considerable length of time. Moreover, it prevents it being easily washed away by the natural secretions.

Mistol and the Mistol Dropper are a real advance in nose and throat therapy. With head tilted back, the patient should let Mistol drop into each nostril until it is felt to be running into the back of the throat. Unlike douches, Mistol avoids any possibility of sinus trouble. It is manifestly superior to salves which do not reach all parts of the mucous membrane.

Sold in original sealed cartons containing a—

FELLOWS MEDICAL MANUFACTURING CO., Inc.
26 Christopher Street, New York, U. S. A.

A safe and simple antacid which is also a gentle laxative must necessarily be of great value to medical practitioners when administering to ladies and children and all who are constitutionally delicate.
May we, therefore, venture to remind you of

DINNEFORD'S

PURE FLUID MAGNESIA

which has been extensively prescribed and used by the Medical Profession for a Century, and is still the best and safest means of administering Magnesia.

When prescribed for the nursery, too, Dinneford's Magnesia has always proved immensely useful as a corrective, and when mixed with infant's food it prevents many of the troubles which are due to acidity, flatulence, etc.

We are confident that you will find in Dinneford's Fluid Magnesia a reliable and safe solution which may be freely used for many ailments, and we would request your kind consideration of its use as occasion offers.

Dinneford's Pure Fluid Magnesia possesses antacid and laxative qualities which are incomparably better than those of any of the various preparations of Magnesia, in powder, now being introduced.

It cannot harm the most delicate constitution and is at all times a safe and effective aperient.

DINNEFORD and CO. LTD.

Regesan

CREAM of MAGNESIA

A pure, finely divided Magnesium Hydroxide ($Mg(OH)_2$), suspended in water. A simple antacid and valuable laxative. Digestive troubles and gastric conditions, indicating the necessity of a corrective of this type, quickly respond to treatment with Regesan Cream of Magnesia. It does not gripe nor cause discomfort, and is mild in action.

VERONIGEN

A liquid preparation of the Hypnotic Barbitone or Diethyl-barbituric acid has long been desired as a useful means of procuring sleep. When given in reasonable doses it is claimed that it does *not produce any* toxic symptoms whatever, nor is cumulative in action, and in ordinary cases of insomnia, *one* fluid drachm of VERONIGEN is sufficient dose for an adult. As a preventive of post-operative vomiting, one to two fluid drachms of VERONIGEN may be given one and a half to two hours before general anæsthesia is produced, and as a result much less of the anæsthetic is required. As BARBITONE has a slight diuretic action, the mixture can be used when the heart is weak. Where *sleeplessness is a concomitant* of pain, rest and relief can frequently be obtained by the administration of one drachm of VERONIGEN and two drachms of ELIXIR ACID. ACETO-SALICYLIC (Hewlett's).

DOSE FOR ADULTS.—One fluid drachm diluted, one hour before going to bed.
For Nervous Sleeplessness in Children.—10 to 20 minims diluted.

VERONIGEN. *Price 10/6 per lb.* In 5, 10, 22, 40, and 90 oz. Bottles.

Introduced and Prepared only by **C. J. HEWLETT & SON, LTD.** Wholesale and Export Druggists

The Complete Antiseptic

Monsol differs radically from all other antiseptics on the market. It attacks *all* germs, whether surface or deep seated, without irritation or injury to the most delicate tissue. Such is its great germicidal power that its effect on the germs responsible for sepsis is ten times greater than that of pure phenol or lysol. Yet it can be applied in effective dilution even to mucous membranes without the slightest risk.

These powerful germicidal properties are possessed by each one of the Monsol products making them the most effective yet produced.

Intestinal Disinfection

ARTERIO-SCLEROSIS

IT is an old adage that a man is "as old as his arteries," meaning that degenerative changes in the arteries are largely responsible for senility.

The modern view is that arterio-sclerosis is produced by increased blood-pressure, and that increased blood-pressure results from the absorption of "pressor" substances developed by putrefactive bacteria in the intestine.

To retard the activity of the putrefactive bacteria, Metchnikoff introduced the soured milk treatment; but how much better it is to use an antiseptic substance. The ordinary so-called intestinal antiseptics, such as Salol, possess little real disinfectant power, and more potent germicides, such as Phenol, are absorbed, and, in sufficient dose, are toxic.

The active principle of Kerol, besides being a very potent germicide, is not absorbed, and is therefore non-toxic. The rational treatment of arterio-sclerosis would, therefore, include adequate intestinal disinfection by means of the keratin-coated Kerol Capsules.

For intestinal disinfection, use KEROL CAPSULES (keratin-coated); they contain 3 minims of Kerol. One to three capsules may be given three or four times a day after meals.

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession.

Food Poisoning—
The Kaylene Treatment

The following letter has been received recently.

Messrs. Kaylene, Ltd.

April 17th, 1929.

Dear Sirs,

I am in receipt of your sample of Kaylene, for which I thank you. I do not dispense and do not wish to be without some in the house.

My last sample was used on a patient suffering from acute Ptomaine poisoning following a meal of shell fish (mussel) at 10.30 p.m. Symptoms first appeared at 12.30 a.m., and when I saw him at 3.0 a.m. he was vomiting blood and passing almost pure blood per rectum. He had commenced cramps and nervous twitchings which would shortly have gone on to tonic convulsions. He was very collapsed and had a weak pulse. I gave him **only** Kaylene in cold water, one drachm every quarter of an hour, from 3.0 until 8.0 a.m., when I felt it safe to leave him. For the next two days Kaylene was given every one to two hours, and was then followed by Kaylene-ol. No other medication of any sort was used, and he made an excellent recovery. This follows a somewhat similar case which I treated at the end of last year.

Your excellent preparation should supplant Bismuth for any purpose.

Yours faithfully,

Physician to ———. ———, M.B.

FACTS CONCERNING THE TERM "LYSOL"

AT the outbreak of the War, the word "LYSOL," which up to that time was the registered trade mark of its originators, Messrs. Schulke & Mayr, of Hamburg, became common property owing to enemy trade marks being expunged from the register.

* * * * *

The original LYSOL formula, however, is still closely guarded, but other formulae have been devised and there are on the market to-day a large number of disinfectants called LYSOL.

* * * * *

As a result cheaper grade disinfectants are being used for purposes for which *nothing* but the very highest quality antiseptic should be even considered.

* * * * *

Owing to the vital nature of the uses to which an antiseptic is put in Midwifery and Surgical cases, it is of the utmost importance that purity and reliability should be the first consideration.

* * * *

Marshall's LYSOL, the product of Lysol Limited, an associated company of the inventors, Schulke & Mayr, is the only LYSOL made strictly in accordance with the original formula.

* * * *

The use of inferior quality antiseptics is a source of great danger, which can be avoided by your specifying MARSHALL'S genuine original LYSOL.

Sample sent on request to members of the Medical and Nursing Professions.

LYSOL LIMITED — RAYNES PARK — LONDON S.W.20

"WHICH EXISTS TO PROTECT YOUR INTERESTS AND SAVE YOUR MONEY."

A British Medical Association Lecture

ON

CARCINOMA OF THE STOMACH.

DELIVERED BEFORE THE SOUTH-WEST WALES DIVISION ON APRIL 17TH, 1929,

BY

A. J. WALTON, M.S., F.R.C.S.,
SURGEON TO THE LONDON HOSPITAL.

Of the 262 patients with carcinoma of the stomach that have sought my advice, 9, and 9 only, have survived for a long enough time for me to regard them as probable cures. These figures are sufficiently startling to make us realize that all is not well with our methods of diagnosis and treatment of this disease. In other varieties of carcinoma somewhat better results are obtained, but they are still far from satisfactory, and for this reason no one disease has at any stage in the history of the medical world attracted so much attention as has cancer to-day. I therefore feel very sensible of the honour which your committee has done me in asking me to consider with you some of the problems which confront us in dealing with the difficult subject of carcinoma of the stomach. On all sides efforts which are almost feverish in their activity are being made to discover its cause and cure, and although there have been no startling discoveries, it is satisfactory to realize that methods which are more or less empiric are little by little adding to our store of knowledge and are steadily improving our results. In some forms of cancer, indeed, the use of radium and x rays has been a great advance on the older methods.

ETIOLOGY.

Carcinoma of the stomach is so difficult to diagnose in its early stages that any improvement in our results must of necessity be slow, and can only be recognized if we have accurate statistical knowledge of the present-day position of the disease. It is generally believed that it is increasing in frequency, but, as I have previously pointed out,[6] my figures do not support this view. They are small in number, but are of value in that every case has been proved by operation, supported either by microscopic examination or by careful observation of the after-progress of the patient. The figures (see Chart 1) show

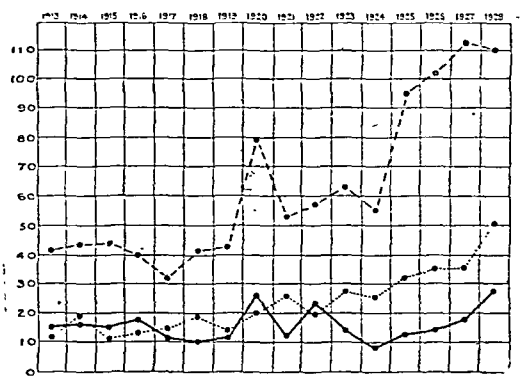

CHART I.—Frequency of carcinoma and chronic ulceration. Total cases of carcinoma 262 (males 191, females 71). Total cases of chronic ulcer 1,141 (males 850, females 291). Continuous line=carcinoma; interrupted line=all ulcers; dotted line=lesser curve ulcers.

a considerable variation in the number of cases treated each year, but no steady or regular rise since 1913. The interesting point is also noticeable that the numbers have remained more or less steady in spite of the fact that the chronic ulcers for which they are often mistaken have shown a very marked and rapid increase in numbers. There has thus been a relative decrease in the numbers of carcinomata, so that whereas in 1913 they formed about one-third of all my gastric operations, they now form only about one-sixth. The explanation which I have given for this, and which I still believe to be correct, is that a large number of cases of carcinoma of the stomach are prevented because they are operated upon while they are still benign ulcers. An apparent increase in the Registrar-General's figures may be due to the fact that the average age of the population is being raised, for the disease is most common between the ages of 50 and 60, more than three-quarters of the cases occurring between the ages of 40 and 70. Nevertheless, it must always be remembered in considering the diagnosis of a gastric lesion that carcinoma may occur at a much younger age. In my own series 3 cases occurred under the age of 30 (Chart 2), but Sullivan,[5] who reported a proved example of the disease in a patient of 22, was able to collect from the literature 21 patients under the age of 25.

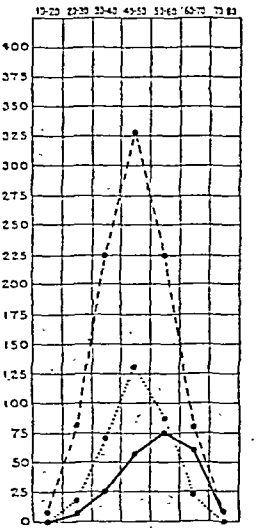

CHART II.—Age incidence of carcinoma and chronic ulceration. Continuous line=carcinoma; interrupted line=all ulcers; dotted line=lesser curve ulcers.

One of the most interesting facts of carcinoma as a whole is the varying sex incidence in the different varieties of the disease. With carcinoma of the stomach the male sex is much more frequently affected. Thus, in my own series of 262 cases, 191 were males. This may to a certain extent be due to the fact that some of the carcinomata are secondary to chronic ulcers, for with chronic peptic ulcers the incidence in males is even more marked. There were, for instance, in my own series of 1,141 chronic ulcers, 850 males.

PATHOLOGY.

Carcinoma of the stomach is almost wholly a primary disease. A few rare cases which are secondary—most frequently to carcinoma of the breast—have been reported, and there are others where the disease has spread to the stomach by direct extension from the gall-bladder, colon, or pancreas. In the viscus itself some of the carcinomata at the cardiac end are squamous in character, and have then almost certainly spread from the oesophageal opening. The softer, more medullary types of such disease may, instead of constricting the lower end of the oesophagus, spread down along the lesser curve and cardia, and give rise to a neoplasm which clinically is gastric rather than oesophageal. To-day this distinction is not of great importance, but if the operation of removal of the cardiac end of the oesophagus becomes more general, the differentiation of these two types will become of considerable practical importance.

The common variety of carcinoma of the stomach arises from the glandular elements, and the different types, therefore, depend upon varying degrees of differentiation of the cells, or upon secondary changes in the host. If the cells are well differentiated they may become columnar in shape and grouped into the form of immature gland tubules. Such a type is spoken of as an adenocarcinoma, and generally forms a fungating mass in the region of the pylorus. There is, however, no sharp line of differentiation between this variety and the more common types. Usually a combination of some columnar cells grouped into incomplete tubules with masses of cuboidal cells is found.

An interesting variety is that in which the cells show a colloidal change to form semi-transparent globules visible to the naked eye. The change appears to be inherent in the epithelium, for it is not only visible in the primary growth, but also in the cells of the secondary deposits. Occasionally masses of unchanged cells are seen lying in large spaces formed of colloid material. Although this

change is generally spoken of as a colloidal degeneration, there is no evidence that it is relatively benign. In the cases in my own series there have usually been large masses of secondary deposits in the coronary glands. Stimson,[4] who studied 121 examples of this variety occurring at the Mayo Clinic, found that they formed about 5 per cent. of all gastric carcinomata, and that the percentage living three and five years after operation was about the same as with the non-colloidal types.

The common pathological types vary in their appearance, if not in their prognosis, according to the reaction of the host and the consequent fibrosis. Those in which there is but little fibrosis are usually described as medullary types. These most commonly occur on the lesser curve, and form large, soft, raised, fungating masses which widely infiltrate the wall of the stomach and frequently ulcerate. There is, however, an interesting variety to which I have on several occasions directed attention. It occurs on the greater curvature of the stomach, grows relatively slowly, and forms a large mass projecting into the stomach, but seems to be relatively benign, and is only associated with secondaries comparatively late (Fig. 1). It is of considerable practical importance in that it may give rise to a relatively enormous tumour, which, because of its size, may be regarded as inoperable, but if an operation be undertaken is found to be easily removable. Owing to its site and rather abnormal characters, it would seem most likely that it occurs as a malignant change in a simple papilloma.

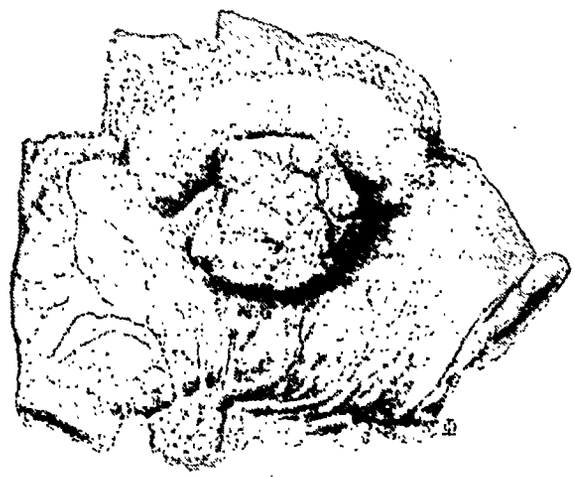

FIG. 1.—Massive carcinoma of the greater curvature of the stomach, posterior aspect.

The scirrhous types with more massive fibrosis are most commonly found at the pylorus, and form smaller masses which infiltrate and replace the walls of the stomach. The fibrous tissue contracts and leads to stenosis, and the mucous surface undergoes shallow ulceration. When situated at the lesser curve it tends to spread round the walls of the stomach, and thus gives rise to an hour-glass deformity, which differs from the common type secondary to an ulcer in that the constricted passage is relatively long and irregular and is centrally placed, so that the greater curve is not drawn up to the lesser as with an ulcer.

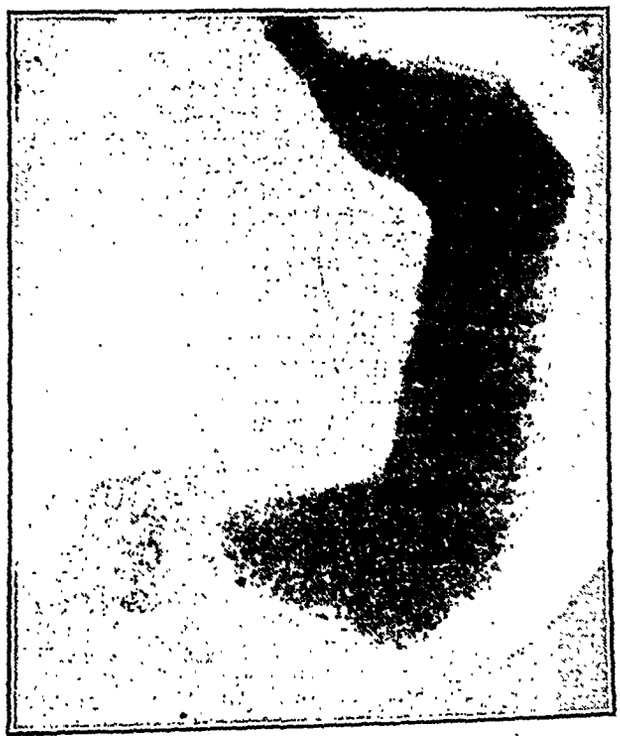

FIG. 2.—Radiogram of "leather bottle" stomach.

This variety of hour-glass constriction may occur with either sex, while the simple type is almost, if not indeed entirely, limited to females, and hence if a male patient is found to have an hour-glass deformity of the stomach a carcinoma should always be suspected. These variations in the reactions of the host are, however, no indication of the malignancy of the condition. A scirrhous carcinoma of the pylorus is not infrequently seen which from its local characters admirably lends itself to resection, but which is associated with widespread secondary changes in the liver or in other viscera. The massive carcinoma of the ovaries, known as the Krukenberg tumour, is usually secondary to a small scirrhous growth of the stomach.

The most extreme degree of reactive fibrosis is found with the condition known as "leather-bottle stomach," or "linitis plastica." It is relatively rare, and my own series only includes four examples. There has been much discussion as to its nature, and a certain amount of evidence has been produced to show that it may occur secondary to an ulcer and be benign in type. Every example in my own practice and in the hospital has, however, been carcinomatous in nature. Sometimes so widespread is the fibrosis that small groups of isolated carcinoma cells may only be found in the stomach wall or in the glands after many microscopic sections have been made. I am therefore of the opinion that all true cases of this condition are of the nature of an atrophic scirrhous carcinoma. The affected stomachs show a remarkable similarity. In the diffuse type the whole viscus is much contracted (Fig. 2), and the wall is enormously thickened and rigid. The peritoneal surface is usually normal in appearance, or may show scattered white patches of infiltration. The change is abruptly limited to the pylorus, and may extend right up to the oesophagus or leave but a small area at the cardia unaffected. Although the stomach lesion is so widespread the change is relatively benign, so that the glands may be but little affected, and the operation of complete gastrectomy, although associated with a high mortality, may hold out hopes of a cure.

FIG. 3.—Stomach from case seen in Fig. 2 after removal (complete gastrectomy).

One of the most important facts which will influence us in the treatment, and especially in the preventive treatment, of carcinoma is its relation to chronic gastric ulcer, a relation which of late years has been the subject of much diversity of opinion. As far back as 1839 Cruveilhier and

Rokitansky first suggested that there might be such a relationship, and later Osler and others found that about 5 per cent. of the carcinomata had originated in such ulcers. Some years later—that is to say, about fifteen years ago—the relationship was regarded as much more close, MacCarty suggesting that some 70 per cent. of all carcinomata commenced in this way. This figure was manifestly too high, and, being disproved, has tended to make opinion sway too far in the opposite direction—an opinion which is fostered by those who believe in the medical treatment of gastric ulcers, for it is evident that if there were a danger of the ulcer becoming malignant the routine use of medical treatment would be a dangerous procedure. Stewart's[3] careful pathological figures are very helpful. He came to the conclusion that 9.5 per cent. of chronic ulcers became malignant, and that 17 per cent. of the cases of cancer originated in an ulcer. I have previously reported a carefully analysed series of 229 of my own cases of carcinoma from this point of view, and have only grouped as having an origin in an ulcer those which fulfilled the following requirements:

1. They must have a history of many years' standing in which the earlier symptoms were periodic.
2. They must have at the time of operation a relatively high test meal.
3. They must present at operation the characteristic appearance of an ulcer.
4. The pathological report must strongly suggest that the carcinoma was secondary to an ulcer.

Twenty-five cases fulfilled these requirements—that is, 10 per cent. of the total—but, as the inoperable cases could not be included, this is almost certainly an underestimate. The more important consideration, however, to us is the percentage of cases which, although not truly benign ulcers, are at first diagnosed as such and later become carcinomatous, for it is in these that the great mistake may be made in continuing medical treatment until the condition is hopelessly inoperable. Scott[2] has laid stress upon this, and has found that 16 to 20 per cent. of clinically diagnosed ulcers become malignant. The importance of the pathological relationship lies in the fact that if we can remove, while they are yet benign, those ulcers which, if left, would become malignant, we shall do much to prevent the onset of carcinoma and to lessen the mortality of this dread disease. Moreover, in our clinical investigations, and in our operations, we must always consider the possibility of such a complication, and if there be any suggestion of its presence a more extensive operation must be performed.

SYMPTOMS.

The symptomatology of carcinoma of the stomach has had so much attention directed to it that it might be thought that it was unnecessary to consider it in detail, but the cases are so often slow and insidious in their onset that they are still frequently overlooked, and it is only by careful consideration of the finer points of the symptoms that an accurate diagnosis can be made, or that even a suspicion of the presence of the disease is aroused. The most frequent variety of carcinoma of the stomach is that which arises in the body of the viscus, and in this position the disease may present itself slowly and insidiously, or arise with a sudden onset, or the symptoms of a gastric ulcer may slowly and gradually change to those of a carcinoma. In the first two varieties the most important factor is without question the presence of a short history of dyspepsia occurring in a patient of middle age who has previously been free of all gastric symptoms, and I am always in the habit of teaching that such a patient must be regarded as having a carcinoma until he can be proved to be free from it. If the onset is slow and insidious, the first symptoms are usually other than gastric. The patient will complain of a general weakness, loss of energy, and inability to concentrate upon his work, a certain amount of sleeplessness, and possibly some loss of weight. It may, indeed, only be on cross-examination that he will acknowledge that there is a loss of appetite, and at a later stage there will be a feeling of discomfort after meals, which may even develop into definite pain. Rarely does this become severe, but it tends to persist throughout the day, although it may be exaggerated by the taking of food. The loss of appetite increases, and is nearly always a marked symptom, until it becomes an absolute distaste for all food.

Vomiting is rarely marked, and frequently only amounts to the regurgitation of a small amount of fluid, which the patient will describe as being foul or offensive in character. Regurgitation of food gives little or no relief to the pain. Blood in the vomit is extremely variable, and is often absent to naked-eye investigation. It is only in a relatively small proportion of cases that the presence of altered blood giving the typical coffee-ground vomit is apparent. A severe haemorrhage is not uncommon, although it is perhaps more frequently found in those cases with a sudden onset. If use is made of chemical investigation blood will be found in a much higher percentage of cases. As the disease progresses the patient will show a steady loss of strength and the onset of anaemia. In some cases the latter is a very marked factor, so that the weakness, the depression, and the loss of appetite are regarded as symptoms of a primary anaemia, and indeed at times the blood count may more closely simulate a primary than a secondary anaemia.

On examination, beyond the anaemia, weakness, and wasting, but little may be found. If there is a tumour it is, of course, suggestive of the presence of a carcinoma, but it must never be forgotten that a considerable proportion of these cases have the lesion high up on the lesser curve, so that a tumour may not be felt until the patient is in the last stages of the disease. On the other hand, the presence of a tumour itself is no indication that the condition is inoperable. Such a mass will be most easily felt when the lesion is seated at the pylorus, and it is this type of case which gives the best possibility of a partial gastrectomy. If the case has been of sudden onset, the patient will much more frequently complain of severe pain. He may be able to date this back to some specific meal, but the pain never disappears, as it would if due to an error of diet. In other cases the sudden onset is due to the presence of severe haematemesis, or, more rarely, to a perforation. The important point always to remember, however, is that, whatever the nature of the onset, carcinoma is much the more likely cause of a dyspepsia arising for the first time in a patient at or about the age of 40. If, therefore, with simple medical treatment, such symptoms have not disappeared completely in a fortnight's time, the patient must not be watched until the diagnosis makes itself evident by the onset of severe symptoms and the presence of a tumour, but immediate investigation with a test meal and x rays must be carried out.

When the disease has arisen secondary to an ulcer, even these methods of investigation may fail, for they may present the characters of the pre-existing ulcer rather than those of a secondary carcinoma. To those of us who believe, as I most certainly do believe, that a persistent chronic ulcer should always be treated by surgical measures, there is much less chance of making a mistake. A careful analysis of the symptoms will reveal the fact that the pain is becoming more continuous though less severe; that the appetite is beginning to fail; and that the pain is not relieved by vomiting. In such circumstances there will be a tendency, which may be increased by the appearance of the lesion at operation, to perform a partial gastrectomy rather than a local operation upon the ulcer.

Test Meal.—In cases of doubt a careful investigation of the test meal will often be of very great help. There is no condition which is associated with so early and complete a loss of the free acid and a diminution of the total acidity. It is true that a gastritis commencing in a man of middle age will often have an achlorhydria, and it may require very careful clinical investigation and consideration of all the evidence at our disposal to make a differential diagnosis. Although more difficult to carry out, a fractional test meal undoubtedly supplies more information than the ordinary Ewald meal, for the acidity is not only low, but there is a complete absence of free hydrochloric acid throughout the whole period of the investigation. The value of this test, if taken for the first time on the patient, must be discountenanced when there has been a previous chronic ulcer. I have had the opportunity on several occasions of examining a test meal on patients who have had a previous meal taken when they still had

a chronic ulcer, and in every case there has been a marked diminution of the acid, but the important point to remember is that although there has been this diminution the acid may still be above normal, and hence if this had been the first meal taken there would have been no indication of the presence of carcinoma.

X-ray Investigation.—It is necessary to-day to issue a warning as to the indiscriminate use of *x*-ray investigation. If the investigation is carried out by a skilled observer and a careful report made of the findings on screening, this is one of the most valuable means of diagnosis at our disposal, but if, as is so often done to-day, one or two films are taken by a man but little versed in the method, the findings are not only useless, but may be positively misinforming and dangerous. In the early stages of the disease an investigation, although performed by a skilled technician, may reveal but little. The most useful sign at this stage will probably be the absence of peristaltic waves over a small portion of the stomach. These may be revealed on the screen, or several films may be superimposed and may show that, whereas the general contour of the stomach is altered, there is a small area which remains absolutely unchanged. In the later stages filling defects, irregularities of the lesser or greater curve and the presence of a large irregular meniscus will, of course, be self-evident signs. A difficulty often arises in the cases that have followed a benign ulcer. There will be a typical picture of the chronic ulcer, and there is therefore a danger that the minor changes, such as occur with the early onset of carcinoma, may be overlooked. It is in such cases that it is so important for the clinician, who has had his suspicions aroused by a slight change in the symptoms, to warn the radiologist of the possibility of the onset of early carcinoma, so that his attention may be directed towards the possibility of slight irregularities in the outline of the ulcer crater.

When the disease commences at the pylorus it will, as a rule, whether of the fungating or scirrhous type, give rise to obstruction, and the symptoms then are no longer characteristic of a carcinoma, but are those of mechanical obstruction; that is to say, there will be the feeling of discomfort and fullness coming on immediately after meals, a certain loss of appetite owing to the secondary gastritis, and the onset of vomiting, which will soon become large in amount and occur at relatively long intervals. Here again the important point to remember is that a carcinomatous pyloric obstruction will only have been present for a relatively short time, whereas one due to an ulcer may have been in existence or have been slowly developing over many years. In any case, obstruction of the pylorus, of whatever nature, should be subjected to early operation.

Carcinoma situated at the cardiac orifice will in the same way lead to œsophageal obstruction, although if the growth has commenced in the stomach rather than in the œsophagus itself there will probably be a period in which the symptoms are those of a neoplasm of the body of the stomach.

TREATMENT.

In spite of a great deal of work that has been done along medical lines, there can be no question that at present such methods hold out no hopes of success. The use of the various colloidal metals—and more especially the theoretically fascinating treatment with colloidal lead—has been relatively widely tried, but cannot yet be said to have made sufficient progress to warrant their general use. Owing to the depth and inaccessibility of the growth, the treatment by massive doses of *x* rays or radium emanations has not yet sufficiently advanced to hold out a very great hope. Possibly in the near future the use of the radium cannon may revolutionize our ideas in the treatment of such growths, but so far this method is in the experimental stage. It may therefore be said that unquestionably the only treatment to be advocated at present is by operation. Because this is an accepted fact, there is rather a tendency to believe that the outlook with such a method is satisfactory. Unfortunately, careful statistics show that even with an operation the results leave much to be desired. To a very large extent the fault of this lies on our shoulders. Of my 262 cases, 171, or 65.2 per cent., were found at operation to be too far advanced for removal, and although early diagnosis is often a matter of great difficulty, we must make every effort to lessen so high a percentage. It is true that many patients show so insidious an onset of the disease that they are in an inoperable stage when they first seek medical advice, but that this percentage can be reduced is shown by my own figures. In the first five years there were 81 cases, 60 of which (74.1 per cent.) were inoperable. In the second 5-year period there was a very satisfactory improvement: of 91 cases, 50, or only 56.1 per cent., were inoperable. In the last five years there has been a slight lapse: of 90 cases, 60, or 66.6 per cent., were inoperable. I cannot help but think that this lapse is due, in part at least, to the recent exalted claims of the value of the medical treatment of chronic gastric ulcers, for so many of this last series had been diagnosed as chronic ulcer and treated medically until they were inoperable.

It is possible that a more extended trial of the method of treating the exposed growth by massive doses of *x* rays, as advocated by Digby Chamberlain,[1] may convert some of the apparently inoperable growths into conditions which can be removed with a good prospect of permanent cure. Even when the growth is removable the end-results are capable of much improvement. The published figures of such results show a remarkable diversity, some having claimed 40 per cent. of three-year and 26 per cent. of five-year cures, whereas others have found that only about 1 per cent. of the operated cases have lived for five years. I have already stated that of my 262 cases only 9 can be regarded as possible cures, and in a series I have previously recorded, of 117 cases carefully followed for a minimum of four years, of whom 62 were treated by partial gastrectomy, only 4—that is, 6.4 per cent.—were still alive and well fifteen, twelve, ten, and seven years respectively after operation, although several of the others who had died of recurrences had lived in comfort for as long as three and four years. It is very doubtful whether this percentage of recurrences can in any way be prevented by the use of more extensive operations. It is my own custom to perform as wide a partial gastrectomy as possible, so that very often only one or two inches of the fundus of the stomach are left, and in many cases the glands are removed from around the coeliac axis. It is in the combined use of radium with partial gastrectomy that at present I am looking for more hopeful results. If only a small percentage of these recurrences can be prevented much may be done to improve the operative results.

Indications for Operation.

Since it is by operating in the earliest possible stage that we can best hope to improve our results and to make it possible to perform a partial gastrectomy in the 66 per cent. of cases which at present are inoperable, we must consider carefully upon what grounds other than a definite diagnosis we are justified in advising operation. It is self-evident that if a patient of middle age presents himself with a short history of persistent and progressive dyspepsia having the characters described above, which has not yielded to a week's medical treatment, and more especially if the test meal shows an absence of free hydrochloric acid, he must be regarded as probably, if indeed not certainly, suffering from carcinoma of the stomach, and an operation should be advised at the earliest opportunity. If the *x*-ray findings are positive or suggestive, the diagnosis may be regarded as certain, but it is especially in these early cases that the *x*-ray appearances may be so nearly normal that a wrong conclusion may be drawn. Although, if an operation be advised with a negative *x*-ray photograph, the patient may occasionally be found to have only a gastritis, yet his relief on being definitely assured that no carcinoma is present is so great that it will do much to help his recovery. In suggesting such a course of treatment one is aware of the danger of advocating a routine exploratory laparotomy, a course which is strongly to be deprecated. It is only after a very careful consideration of the symptoms and of the danger of overlooking a carcinoma that an operation should be advised. If the case has been one with a sudden onset and presents the more serious symptoms of haemorrhage or severe pain, operation can even more confidently be advocated. The condition is then

almost certain to be one of carcinoma, or in a very few cases where there has been an error of diagnosis the underlying condition is most probably one which can only be treated by operative measures.

When the patient has been suffering from a chronic gastric ulcer which has undergone a change in the symptoms suggestive of the onset of carcinoma the course to be pursued is definite. So long persistent an ulcer giving such definite symptoms ought never to have reached this stage before an operation was undertaken, and the difficulty before the surgeon will be, not whether to operate, but whether to carry out a more extensive partial gastrectomy because of the suggestive symptoms. In this type of case the test meal may still be normal, and the radiogram may be characteristic of an ulcer; but there should be no hesitation whatever, if there is the slightest suggestion of a carcinomatous change, either because the symptoms have become more persistent or less severe, or the appetite has begun to fail, or the vomiting has altered in character and does not relieve the pain, in performing a partial gastrectomy on the assumption that a carcinomatous change is present. I have unhesitatingly pursued this course, and have never had reason to regret it. In some 10 cases the removed portion of the stomach has shown to the naked eye a characteristic chronic gastric ulcer, but subsequent microscopic investigation has revealed the presence of a carcinomatous change, and the operation therefore has given the patient the chance of a permanent cure. If there is pyloric obstruction, operation must always be performed at the earliest opportunity, for it is evident that if a patient of middle age has developed a mechanical obstruction nothing but surgical treatment can overcome the trouble. Nevertheless, cases are still seen where medical treatment, including lavage and diet, has been carried out for some weeks or months until the condition has become hopelessly inoperable. In this variety, as in the last, a careful consideration must be given to the symptoms, and if there is the slightest suggestion that the obstruction is carcinomatous in origin a partial gastrectomy must be carried out rather than a gastro-enterostomy. The only difficulty which will arise is in those cases where there has been a long past history of a pyloric ulcer, for a short history of pyloric obstruction in an adult is almost certainly carcinomatous. When secondary to an ulcer the main points upon which a differential diagnosis will be made are the rapidity of the onset of the obstruction, the relatively early fall in the acid in the test meal, the loss of appetite, and the presence of a tumour.

The mere presence of a tumour in the region of the stomach is no counter-indication to operative treatment, nor, indeed, is its size or apparent mobility. It may be thought that the tumour is so big that it is certain to be inoperable, but massive carcinomata may occur on the greater curvature which give rise to a tumour 3 to 4 inches in diameter and yet are easily removable. The only counter-indication to operation in a tumour of this nature is the definite evidence of secondary deposits. Most frequently they show themselves as nodules in the recto-vesical pouch, which can be felt by rectal examination, as enlargements of the liver, or in the presence of ascites. It is true that the larger the tumour and the more fixed it appears to be the more likely is the case to be inoperable, but it has always been my experience that in doubtful conditions it is wiser to carry out the operation. Should this not be performed the relatives will always feel, after the death of a patient, that if only an operation had been carried out he might have been saved, whereas when it has been performed and the condition found to be inoperable they will consider that at least every attempt had been made to save him.

Of the technical steps in performing the partial gastrectomy I need say but little. There should be a wide and free removal of the lesser and greater omenta. The subpyloric glands around the head of the pancreas must be carefully dissected away. The coronary group of glands must be removed as high as possible, and it is my own custom in cases of doubt to dissect the glands from around the coeliac axis. The resection of the stomach should in all cases include about seven-eighths of the viscus, and the anastomosis can be best performed by the end-to-side method of Polya. It is my own custom to do this by the old method of bringing a loop of jejunum up through the mesocolon, and making the anastomosis some 4 to 5 inches from the flexure. Many surgeons have abandoned this method and make the antecolic anastomosis, but in my hands the posterior method—if a small loop is left—is so satisfactory that I have seen no reason to change it.

It will naturally be thought that with the modern progress of radium treatment some use may be made of this form of therapy, but with our present uncertainty of the results of this method of treatment it has seemed useless to attempt to use it in the advanced and inoperable cases, for this would mean a wide application to the stomach, to the glands, and probably to the liver, but it does hold out a hope that if used in combination with operation it might do something to prevent or lessen the high recurrence rate. It has been my experience that the cases which recur usually show a large deposit either around the head of the pancreas or in the neighbourhood of the coeliac axis. I have therefore in my more recent cases been using radium after all partial gastrectomies, and have been inserting 12 milligrams around the coeliac axis and 8 milligrams around the head of the pancreas. These tubes are left *in situ* for four days. It is, of course, at present impossible to say what the value of this method will be, and indeed we shall not have any accurate statistics until at least five years have elapsed. Our present experience does show, however, that the insertion of the tubes may cause a little post-operative vomiting, but so far this has not been sufficient to make us abandon its use, and we still have high hopes that satisfactory results will ensue and that the number of lasting cures will be considerably increased.

SERUM TREATMENT OF THE PNEUMOCOCCUS PNEUMONIAS.*

BY

JESSE G. M. BULLOWA, M.D.,

CLINICAL PROFESSOR OF MEDICINE, NEW YORK UNIVERSITY.

CLINICAL classification of the pneumonias in accordance with their probable pathological findings seems to be useful only in so far as they suggest the etiology. Such classifications may prove clinically disastrous, as when a diagnosis of broncho-pneumonia or "influenza pneumonia" is made, and the actual condition is Type I pneumococcus pneumonia. Such cases are common. Two were recently investigated by us; both proved fatal, and were due to pneumococcus Type I, and therefore probably amenable to serum therapy. They were not typed until they came under our observation very late in their course.

Etiological classification of the pneumonias is of value if it helps to determine treatment and prognosis. Until it was definitely demonstrated that serum treatment was useful in at least one of the pneumococcus pneumonias a further subdivision of the miscellaneous types of organisms that constitute the miscellaneous group, or Group IV, was, for practical men, scarcely worth the effort involved in separating them.

As the result of the carefully controlled experiment at Harlem, Bellevue, and New York Hospitals, carried on under the direction of Dr. William H. Park, it has been shown statistically that in Type I pneumonias the mortality can be reduced by the use of the refined antibacterial serum now available, so that instead of one patient in three, one

* Read before the Eastern Medical Society, February 8th, 1929. From the Medical Service, Harlem Hospital (Lewis K. Neff, Director) and the Littauer Pneumonia Research Fund of New York University.

patient in five dies. Though the statistics are not as definite in Type II cases, instead of one patient in three, one patient in four dies. A relatively useful serum for Type III pneumonia is not available.

As the result of the studies of Dr. Park and Miss Cooper, the patients at Bellevue and Harlem Hospitals are classified according to type; for this purpose thirteen different types are recognized. Dr. Park, Dr. Rosenblüth, and I gave the statistics of our service during the past two years at Harlem Hospital, and the other hospitals associated with us, in a paper in the *Journal of the American Medical Association* of November 17th, 1928. In brief, our results showed,—in Type I cases, a reduction of fatality of 42 per cent., with a ratio of difference to standard error of 3.7 (regarded by statisticians as statistical proof), and in Type II cases a reduction of mortality of 22 per cent., with a ratio of difference to standard error of 1.9.

At Harlem Hospital we have treated alternate patients in the order of their admission, rating them on their arrival in the ward, and we have employed a standard method of management which applied to both the serum-treated cases and the cases not treated with serum.* As the result of our observations we were convinced not only that there were fewer deaths in the serum-treated cases, but that we saved patients who were more seriously ill, and shortened the time of their illness.

Satisfactory as were our results in the hospital and private practice, there can be no great reduction in pneumonia deaths in general until the serum is promptly applied by the physicians in practice throughout the community. It is only a relatively small number of pneumonia sufferers that are at the present time taken from their homes. While physicians were without any effective therapy to offer to their patients a policy of watchful waiting, with so-called supportive treatment, was justified, and, depending upon his limited experience in the particular season, the practitioner has felt either that his efforts were of value, or that the disease was especially virulent.

So long as it was necessary to spend hours desensitizing patients to unrefined horse serum, when frequent and severe serum sickness was the rule, and when large quantities of horse serum of unknown titre had to be injected, it was only to be expected that the serum treatment would remain a procedure limited in application to those hospitals in which exceptional facilities were available. Unless the diagnosis of Type I infection (for which the serum was intended) was made, injection of the serum was unjustified. At present there is in use a serum of strong titre, freed from most of its deleterious ingredients, and concentrated so that an efficient dose can be administered in the home after brief preliminary tests; the serum treatment has thus become available for the general practitioner.

With the successful introduction of the serum treatment of pneumonia we may hope for results equivalent to those which followed the employment of antitoxin in diphtheria —a marked reduction of the death rate from the pneumonias and a great improvement in the technique of preparing serum, with an increased skill in application; in other words, better typing and dosage. At present polyvalent serum is available in titres as strong as 3,000 units of Type I, and 15,000 units of Type II, and I have used serums as strong as 5,000 units per c.cm. A well-refined high titre serum, which has been freed of all chill-producing substances, is the aim of serum manufacturers. The Research Laboratory of the Department of Health, the Littauer Pneumonia Fund of New York University, and the Harriman Fund are directing their efforts to the production of such serums. The methods of refining are technical chemical processes which little concern the clinician.

With increased knowledge and with more funds, therapeutic serums for the more recently separated types will become available, and will no doubt prove as efficient in practice as they are in laboratory experiments. As long as we depend upon type specific therapy, methods for improving and hastening the determination of the invading type of pneumococcus must occupy our attention.

Recently one of our workers, Mr. Albert B. Sabin, a student in the medical school of New York University, has developed an important improvement in the typing of pneumococci which may, in the 90 per cent. of cases apparently insusceptible to typing by the Kumwiede method, shorten the time of typing to as little as three hours. This method requires only few organisms. It has the further advantages that it requires little serum and can be performed without the elaborate arrangement of tubes and controls required in the usual agglutination and precipitation tests. The method, which will be published shortly, depends entirely upon the microscopic agglutination of organisms on a slide; it has been used in upwards of 100 cases and carefully checked with the older methods, and up to the present time there has been complete agreement.

This brings us to a discussion of the whole question of typing. Occasionally a report is received of one organism having been obtained from the sputum and another from the blood stream of the mouse, but it is most important to realize that, although the finding of one organism in the sputum may be reported, yet the patient is invaded by a different organism. For this reason blood cultures should be taken from all patients suffering from pneumonia, and the organisms recovered should be typed. In our experience* a positive blood culture has been found in 22 per cent. of all cases. The information thus obtained is not one of mere theoretical interest. A positive blood culture in a patient definitely defines the type of the invading organism, and also determines the need for increased intensity of treatment, if the invader be a Type I or Type II organism. Rosenblüth showed that the greatest benefit from serum, in our cases, was in the patients in whom a bacteriæmia was demonstrable. However, in the absence of a positive blood culture the sputum should be typed; and when that is not available, swabbing from the gagged throat should be typed, because lung secretion may not be expectorated but swallowed after passing through the larynx.

In the absence of a positive blood culture and of evidence that there is a type specific invasion, or before it has been definitely proved that the organism recovered from the mouse's heart's blood is not Type I or Type II, for which the polyvalent serums are available, it seems safest, in the interest of the patient, to administer the serum we have for Types I and II, until antibody for these types appears. The very rapid disappearance of one antibody suggests its utilization by an invading organism. The administration of serum has apparently done no harm to those for whom it was not beneficial.

In our general experience more than 55 per cent., or more than half of the cases, are Type I or Type II. During the thirty-six hours which may elapse before the typing can be definitely determined valuable time and even life may be lost. There is nothing so disheartening as to find that a patient for whom a serum was available has died untreated with serum. It is just the same as if one were to withhold diphtheria antitoxin pending a throat culture report. Just as one sees patients die of diphtheria when the throat culture is reported negative, so one finds cases of Type I or Type II pneumonia get into such a condition that serum is unavailing when the report from the mouse peritoneum is Miscellaneous or Type X, and serum has been therefore withheld. On our service at Harlem Hospital serum, as stated above, is given to alternate cases on admission, and continued until the report from the typing of the mouse blood culture has been received. It is discontinued only when that is reported Miscellaneous or Type X.

There are errors inherent in the usual gross method of typing, as a result of which serum is occasionally given uselessly. These may be corrected by the more refined techniques. Some of these problems will be solved in time, and inaccuracies of diagnosis will become less frequent.

The Sabin microscopic typing method promises to prove a useful instrument, but more important than its use in

* The serum used is so concentrated that it contains usually 1,000 units of each of Type I and Type II per c.cm.; 10,000 units of each type is injected intravenously; the dose is repeated every eight hours until the temperature is below 102° F., or the presence of the specific type of agglutinin can be demonstrated by the Sabin method. Severe cases have larger and more frequent doses.

* The method of blood culture is described by Rosenblüth in his paper.

the diagnosis of type is the converse application—that is, the detection of antibody in the patient's serum with blood obtained from a finger puncture, and of the presence of sufficient antibody of the types for which the serum is intended. In this way serum may be injected more frequently or continued less long, and possibly, if the typing is reliable, crises may be predicted. It is true that this method depends upon the assumption that protection and agglutination are present simultaneously. It has not been our experience that agglutinins have not been present in the absence of protection. A case will be described later which illustrates this point, in which serum was administered and the formation of antibody by the patient was demonstrable later in the disease. It is waste of time to continue to use serum after there is ample protection present, for that is all that the serum can do. The patient may die from anoxaemia, from pulmonary oedema, or collapse, or from other causes, but after protection is present in the blood the administration of further serum is utterly wasteful.

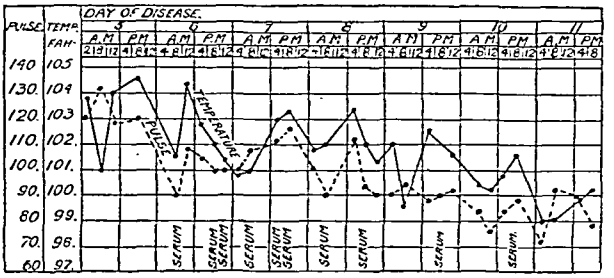

CHART 1.—Case IV.

The serum treatment is not yet perfected; there are still patients who die in spite of serum, and it is these patients who are especially important for further study.

I give below the case records of a number of patients treated at the Harlem Hospital, so that you may understand our difficulties, and realize our satisfaction with what is being accomplished by the use of serum: and understand, too, our eagerness to have the serum treatment penetrate into private practice, so that the death rate from pneumonia shall be lessened. There were 9,951 deaths from this disease in New York City during 1928. If only 30 per cent. were amenable to, and treated with, Type I and Type II serum, the saving would be impressive. The time must come when the serum will be provided by the municipalities, and there is no reason why, with the present widespread use of intravenous medications, blood cultures should not be taken by practitioners and studied for them at the municipal laboratories.

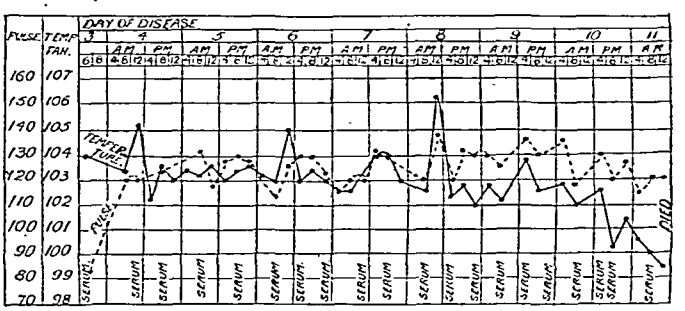

CHART 2.—Case VI.

CASE I.—*Type I without Bacteriaemia.*

An obese female, aged 30, came into hospital on the fourth day of illness with a temperature of 104.6° F. Her blood culture was negative. She received 30,000 units of Type I, and 15,000 units of Type II antibody, in a single 10 c.cm. intravenous injection. The serum was administered before determining the type—both peritoneal exudate and mouse's heart's blood were Type I. This case shows the result to be expected with a large dose of serum.

CASE II.—*Type I with Bacteriaemia.*

This patient, a physician, came in on the third day of his infection with a temperature of 106° F. His blood culture showed fifteen and three colonies per cubic centimetre on two agar plates. He received 14,000 units of Type I antibody that day; his temperature fell after the first dose. The next day he received, in three doses, a total of 48,000 units; the following day he received 24,000 units. On the sixth day of his illness, antibody, by the gross (Arlyle-Noble) method, was positive. He received on that day 63,000 units. The report came too late for us to be guided. The blood culture, taken on the second day, was negative. After the sixth day he was convalescent. The sputum was Type I in mouse peritoneum and heart's blood.

CASE III.—*Type I with Bacteriaemia.*

This patient came in originally as a non-serum case. (We are still alternating patients, but patients with Type I pneumococcus bacteriaemia are now being given serum, as we have already adequate proof of its value to them.) The culture taken on admission was positive in the broth; the next day he received three doses of 30,000 units of antibody. The blood culture, taken before serum was begun, showed five and four colonies per cubic centimetre. His temperature fell to normal on the fourth day, but rose that evening. His blood culture continued negative. Nevertheless, as his temperature was much elevated, he received an additional 120,000 units during the next two days. At that time we were using a temperature above 102° as the exclusive guide to repetition of dose.

CASE IV.—*Type I with Bacteriaemia.*

This was also a non-serum case. He had five colonies in one plate, and the broth was positive on the fifth day. The next day he received serum in divided doses, 76,000 units. His blood culture was positive in the broth. On the seventh day his blood culture was negative. He received 76,000 units the first day, 60,000 units the second day, and 20,000 units after that. The serum given on the ninth and tenth days was unnecessary; but we did not know that the blood taken for antibody on the ninth day had ample agglutination and protection. This case apparently reveals a late invasion of the blood stream followed by recovery, showing the value of serum later in the disease. (See Chart 1.)

CASE V.—*Type I.*

This patient came in as a serum case. His blood culture was negative. He received 30,000 units of Type I antibody, and on the eighth day was still so ill that he was placed in the oxygen chamber. His temperature continued elevated. He was delirious. His pulse was of poor quality—128 per minute. On the ninth day of his illness, at 10 a.m., he received 30,000 units; at 6 o'clock that evening, when the next dose was due, a Sabin microscopic antibody test was performed. It showed agglutination of Type I antigen, and also of Type II. There was more clumping at 8.45 p.m., and still more at 11 o'clock that night. Serum was withheld. The next morning the temperature was normal and the patient was clear. This patient was thus shown to be developing his own antibody.

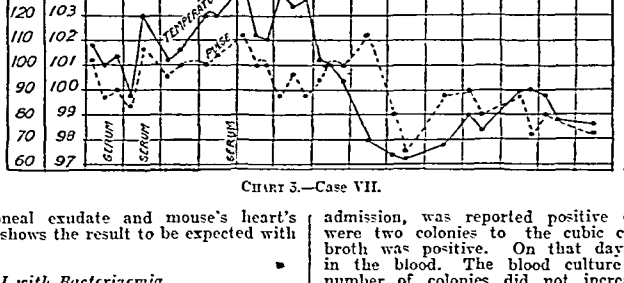

CHART 3.—Case VII.

CASE VI.—*Fatal Type I Bacteriaemia treated with Serum.*

Not so fortunate is the result in the next patient. He received serum from the day of admission. The dosage was not large; he was given 15,000, 22,000, 24,000, and 20,000 units. The blood culture, taken on the day of admission, was reported positive on the seventh day. There were two colonies to the cubic centimetre of blood, and the broth was positive. On that day no antibody was detectable in the blood. The blood culture continued positive, but the number of colonies did not increase. In spite of the large dosage there was no antibody detectable on the eleventh day, the day on which he died. In this case it is probable that the antibody was used up as fast as it was introduced. With the Sabin method it may become possible to give antibody so rapidly that an excess will be detected and patients saved. (See Chart 2.)

CASE VII.—*Type V Bacteriæmia with Recovery.*
This case belonged to Type V; the blood culture was positive the eighth day, though the temperature was below 102°. This tient either sterilized his own blood, or there was sufficient otection for Type V associated with the Type II serum. There ere probably only 400 units of Type V protection given in the rum. (See Chart 3.)

CASE VIII.—*Type V Bacteriæmia mistaken for Type II: Fatal.*
This patient was a married woman who, on the third day of r illness, had a positive blood culture and sputum; the organism as reported from another laboratory as Type II. On the fourth ay she had a miscarriage at eight months. She received large oses of Type I and Type II serum. On the fifth day there was mple antibody for Types I and II. Her blood culture continued ositive; the serum was unavailing. The original blood culture, hich had been reported Type II, was then re-typed, as well as blood culture after ample antibody for Type I and Type II ad been administered and was demonstrable in the blood, and vas found to be actually Type V.

CASE IX.—*Type II Bacteriæmia: Fatal—"Influenzal Pneumonia."*
This patient came in on the influenza service of the hospital. When a consolidation was discovered on the sixth day a blood ulture was taken. He was given 15,000 units of Type II serum, nd was placed in the oxygen chamber. Serum was administered more actively—as much as 60,000 units, 80,000 units, and 30,000 units being given. In spite of this intensive treatment antibody was not detectable in his blood. The colonies in his plate did not increase, but he continued to become more poisoned, and finally died on the twelfth day of his disease. It is probable that, in this case, if more intensive treatment had been given at the very onset, sufficient to produce a positive agglutination test and maintain it, the result might have been different.

It will be seen from these cases that the problems connected with the serum treatment of pneumonia are numerous. Many of them are unsolved. Those of us who are working in hospitals, with ample laboratory assistance, have much for which to be grateful. I have shown the difficulties so that it should not be assumed that the serum treatment of pneumonia is a finished chapter; but I have also shown the triumphs, so that practitioners may be impelled to use serum in the treatment of their patients. If it is employed generally, so that the toll of pneumonia is lessened, as I believe it will be, the purpose of the Littauer Pneumonia Research Fund of New York University will be accomplished, and those who have devoted themselves to these problems will know that they have not worked in vain.

THE CARE OF RHEUMATIC CHILDREN.*

BY

A. DINGWALL FORDYCE, M.D., F.R.C.P.ED.,

HONORARY PHYSICIAN, ROYAL LIVERPOOL CHILDREN'S HOSPITAL, AND TO THE BIRKENHEAD AND WIRRAL CHILDREN'S HOSPITAL.

For the past three years I have held, both at the Liverpool and the Birkenhead Children's Hospital, a special out-patient clinic for rheumatic children; to this clinic school medical officers have sent considerable numbers of cases, and practically all children have been recommended by doctors. Through the co-operation of the respective child welfare associations home conditions have been investigated and reported upon, and regular supervision of the children obtained. Most of the children have passed through one or more of the in-patient branches of the Liverpool or Birkenhead hospitals, and their supervision continued thereafter. Acute cases have mainly been dealt with in the city hospitals, while long-continued residential care has been carried out in the Heswall and West Kirby institutions. Most of these latter cases have been at the Heswall Hospital, some for many months, and all have had the benefits of special schooling and graduated exercises in addition to medical and nursing care. The physical condition of the children has been investigated as fully as possible, and attention paid both to general treatment and as regards points of focal infection. Reports have been sent to the respective chief school medical officers dealing with the actual physical condition—and particularly the condition of the heart—and recommendations made as to the desirable nature of school attendance or type of school.

Up till March 31st of this year 540 children had attended, a few of them since before the commencement of a special clinic and the others for varying periods since. At this date (March 31st) these cases could be classified thus: 321 children with apparently no permanent cardiac lesion, 119 children with an apparently established cardiac lesion but with satisfactory myocardial response, 25 children in whose cases I was still uncertain as to whether cardiac damage was permanent or not, 41 children with cardiac lesions and failing heart, 9 cases of death from rheumatic carditis, 9 children suffering from acute rheumatic fever, and 16 cases of congenital heart deficiency.

Excluding cases of congenital heart deficiency and all cases suffering at the date (March 31st) from acute rheumatic fever, the outcome of whose illness hung in the balance, and giving the benefit of the doubt in prognosis to all cases of doubtfully permanent cardiac lesion, I find that of 515 cases medically recommended to the clinic as rheumatic, and accepted by me as such, 346 could be regarded as suffering from no permanent heart lesion, 119 definitely had a permanent lesion but showed good response, 41 showed evidence of failing heart muscle, and 9 had died. In other words, 50 children—10 per cent. of cases—had died or were unlikely to survive childhood, and another 119 children—25 per cent. of cases—were permanently crippled to a greater or less extent.

I put forward these figures with no further object than to show that rheumatic infection in childhood is a common and dangerous disease on Merseyside, and I cannot be accused of making a case for the rheumatic child, as these children were all sent to me as rheumatic or suspected rheumatic. During the first three months of this year—to March 31st—273 children attended the clinic on one or more occasions, and the average attendance was about 25.

In all, approximately 400 reports have been sent to the chief school medical officers, the form of each report being as follows:

RHEUMATISM AND ACQUIRED HEART DISEASE.

Name..... *Sex*..... *Date of Birth*.....
Address..... *School*.....
Place of Examination.....
History, symptoms, and physical signs.....
.....

CLASSIFICATION OF CASE:

A.—Acute pyrexial rheumatism.
B.—Acute chorea, i.e., chorea of less than two months' duration.
C.—(1) Rheumatism or chorea other than that included in A or B; with no heart lesion, or apparently curable heart lesion.
(2) Apparently permanent acquired heart lesion—good prognosis.
(3) Apparently permanent acquired heart lesion—bad prognosis.

RECOMMENDATIONS:

1.—Fit for Public Elementary School.....
A.—No restrictions.
B.—No violent games.
C.—No drill or gymnastics.
2.—Fit for Special P.D. School.....
A.—Day School.
B.—Residential School.
3.—Not fit for any School..... Period of exclusion.....

Signature of Examiner.....
Date of Examination.....

* A paper read at a meeting of the Liverpool Division of the British Medical Association.

These recommendations are sometimes not acted upon by the authorities because the facilities do not at present exist, but I hope they may assist ultimately in the framing of schemes for administrative advance. The number of cases is large, and their continued supervision a matter of very considerable difficulty.

The serious figures I have given, showing that in 35 per cent. of the cases death or permanent cardiac crippling supervened, may be subjected to criticism from two aspects. In the first place, it can be urged that chiefly serious cases were sent to the clinics, and this is no doubt true to some extent. But it is not altogether so, because school medical officers were informed that it was *rheumatic* children with whom it was desired to deal, and they knew that the underlying effort was the prevention of heart disease. The other criticism that can be put forward is that these children were not efficiently cared for. This criticism I also, regretfully, accept in part, and shall deal with some details in a moment; but this must now be said—that exceptional care and attention have been paid to these children, no pains have been spared in their treatment, and in many instances the degree of their improvement has been remarkable. I am definitely of opinion that the development of specific rheumatic clinics with associated home visitation and regular supervision has improved the prognosis.

There are some cases in which we are forced, in spite of every conceivable form of treatment and all facilities, to watch the child passing from the early infected period to that of grave cardiac disease and ultimately death. But such cases should be rare, and are rare if the early signs of the first active infection are noted and dealt with. When these early signs are noted close care for a prolonged period is essential. But in a series of 52 consecutive cases of acute rheumatism recently admitted to the Children's Hospital, Liverpool, in only 18 instances was it possible for direct transference to another institution—country hospital or convalescent home—to be carried out, while of the total 52 cases 75 per cent. were retained in the City Hospital for only a month or less. Efficient therapeutic prophylaxis was here evidently not carried out; but, owing to the need for beds in town for acute cases, it is impossible to retain these children in city hospitals, and sufficient accommodation is not provided for them in country hospitals. Many patients have to wait months for admission to the Heswall Hospital, and frequently such waiting period leaves marks of serious damage.

The new Local Government Act will bring about many changes and open up many possibilities. I am sure that no more important development can occur than the setting aside of specific beds or wards for the prolonged care of rheumatic children.

As regards the active care of the children, I would lay great stress on the removal of infected tonsils. Of the 531 rheumatic children alluded to in this paper, 130 underwent tonsillectomy in hospital and 22 at a school clinic; in 4 cases parents refused permission for operation, and in 67 cases operation is desirable and probable. Thus in 213 out of 531 children—or about 40 per cent. of cases—I have considered tonsillectomy advisable.

Contrary to what some may think, I consider that in being responsible for these figures I have acted in a conservative manner. I have considered as indications for operation:

1. Obviously unhealthy tonsils—irrespective of size.
2. The presence of rheumatism with a history of tonsillitis as initial symptom.
3. The presence of rheumatism with recurring attacks of nasopharyngeal catarrh associated with exacerbations of active rheumatism.
4. Cases of active rheumatism running a prolonged course resistant to all medical measures, whatever the appearance of the tonsils.

In none of the cases operated on did unfavourable symptoms develop from the operation, however active the rheumatic symptoms at the time; while in most cases obvious and marked benefit accrued. It is, however, impossible to consider the operation as an isolated factor in treatment, as good results from it can only be justly expected when enucleation is complete, when the immediate after-care of the child is as thorough as after a major operation—which this is—and when, after suitable institutional care, home supervision is so prolonged as to tend to prevent or at least deal early with subsequent intercurrent infections.

I cannot but feel that the term "acute rheumatism" in childhood has been stressed unduly in the effort to obtain accurate delimitation. Our foe is *active* rheumatism, and, perhaps unfortunately, its symptoms are not always acute. It is usually easy for the clinician to make a diagnosis between rheumatic infection and the varied rheumatoid conditions; and syphilitic cardiac conditions are rare at this age. It is the early diagnosis of active rheumatic infection which is so important, which is sometimes difficult, and which, I think, is sometimes delayed because of the common use of the term "acute" rather than "active."

The early diagnosis and suitable care of active rheumatism give good results. Fortunately for the children of the well-to-do, frequent medical supervision and constant educated home care serve to prevent acute ebullitions and disastrous end-results even without the need of accurate diagnosis. For, however, the children of the hospital class, once they show symptoms of active rheumatism, and whether they have been previously classed as "dyspeptic," "hypoglycaemic," "pre-acidotic," "intestinal," "toxic debilitated," or simply "pre-rheumatic," I consider the value has been fully demonstrated of specific hospital clinics and associated home visitation and prolonged supervision by private practitioner or through the clinic.

I also consider that tonsillectomy, efficiently carried out and succeeded by suitable and prolonged care, takes a very important place in treatment, and that the need of adequate institutional beds for prolonged care is clamant.

HYSTERO-SALPINGOGRAPHY IN THE DIAGNOSIS AND TREATMENT OF STERILITY AND PELVIC DISEASE.*

BY

R. S. STATHAM, O.B.E., M.D., CH.M.,

HONORARY GYNAECOLOGIST, BRISTOL ROYAL INFIRMARY; LECTURER IN OBSTETRICS, UNIVERSITY OF BRISTOL.

In a previous paper on the subject of sterility[17] I emphasized the great importance, in all cases where no definite cause could be found for lack of conception, of ascertaining the patency of the Fallopian tubes before treatment was begun. At that time I was using the Provis-Rubin method of CO_2 insufflation, and I instanced two cases of pregnancy following on the clearing of the so-called "sticky tube"; since that date I have met with four further successful cases, in each of which the patient became pregnant within six weeks of the insufflation. The object of this paper is to further the claims of a method of diagnosis and treatment which is, in my opinion, far superior to the gas insufflation, good though that is. This procedure consists of injecting lipiodol into the uterus and tubes under the control of an *x*-ray screen, and then the taking of a series of skiagrams. It is equally valuable in diagnosis and treatment.

Before coming to the technical details it may be of interest to give a short history of this method of diagnosis. As far back as 1914 Carey[6] in the United States attempted to pass collargol through the tubes, but got no practical negatives, while Dimier in Paris recorded a death while using the same procedure. These results caused the method to be abandoned. In 1915 Rubin[15] published a paper on collargol injections. In 1923 Kennedy[13] made use of sodium bromide, and in the same year we also tried it at the Bristol Royal Infirmary: but these methods gave poor and unreliable results, and a few cases of peritonitis were recorded.

The discovery of the suitability of lipiodol for the injection material was the means of establishing this technique on a sound basis. Carlos Hueser[11] and Carelli,[5] during

* From a lecture with lantern slides delivered to the Bath and Bristol Branch, February 27th, 1929.

1924 and 1925, produced a series of beautiful photographs of the injected uterus and tubes, and soon afterwards this method of diagnosis was taken up enthusiastically on the Continent and in America. Gynaecologists in this country, with the notable exception of Forsdyke,[10] have, for some reason, fought shy of this most useful help to diagnosis and treatment. A flood of literature has recently resulted, especially in France, where Béclère[2, 3] has produced several papers and a most useful and indeed invaluable monograph[4] on the subject. As a few typical papers I would mention those of Cotté,[7, 8] Sicard and Forestier,[9] Randall,[14] Rubin,[15, 16] and Jarcho.[12]

Complete details of technique and results, and a very full bibliography, can be found in Béclère's book. He quotes 168 authorities, and I am much indebted to this very complete list of authors. It is of interest to note that I have been able to find only three cases of any ill results following lipiodol injections, one reported by Rubin, and two by Béclère in the *Bulletin de la Société Obstétrique et de Gynécologie de Paris* for February, 1929.

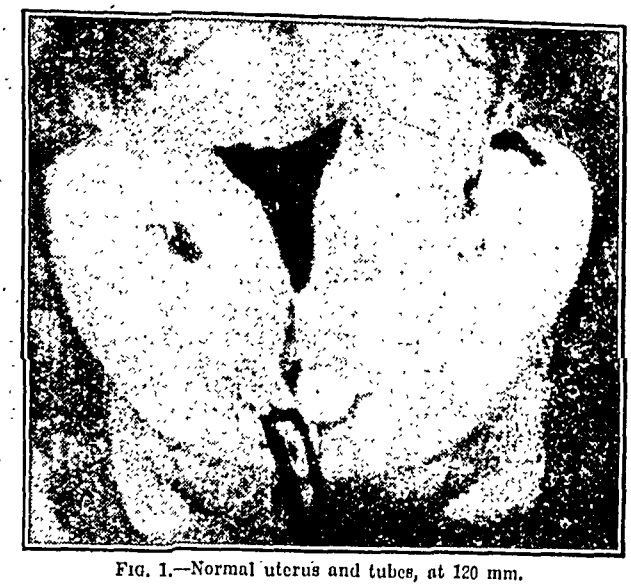

FIG. 1.—Normal uterus and tubes, at 120 mm.

Technique.

The patient requires no special preparation unless an anaesthetic is to be given, but it is most important to make the test at least a week from the beginning or end of a menstrual period. Pregnancy, purulent cervicitis, and active salpingitis are contraindications. Although the discomfort is not very great, and is a most useful check on the pressure used, I employ a general anaesthetic for nulliparae and for very nervous patients, for the reason that the whole test may be spoiled if the patient jumps and the lipiodol runs out from the vagina and up her back, thus making a dense shadow to the x rays. In many cases I find a small dose of morphine and scopolamine a great assistance. I use a special syringe made for me by Messrs. Allen and Hanburys, modified from that of Dr. Bloch-Wormiser. It consists of a 25 c.cm. metal syringe, with a screw-in piston, which delivers 1 c.cm. of lipiodol to each complete rotation of the handle. The pressure is registered on a manometer, which has a luminous dial, so that it can be read in the dark of the x-ray room. There is an oil lock with sliding piston between the lipiodol and the anaeroid, thus preventing the latter being injured by the lipiodol. The oil lock is kept full of liquid paraffin, and this occasionally needs refilling owing to seepage. A swinging side tube with a three-way tap action permits the syringe to be refilled without removing the nozzle from the cervix, which is most useful in dealing with enlarged uterine cavities—for example, fibroids. The nozzle itself is strongly made of metal, and is quite short and blunt, with the hole at the side and not at the tip; the taper of the cone allows it to fit well in cases of laceration of the cervix, and the short tip gives rise to no trouble if the uterus is sharply anteflexed. To perform the test the syringe and nozzle are filled with lipiodol at blood heat (warming it lets it run much more easily). The patient is then placed upon the x-ray screening couch, lying on her back. If an anaesthetic is now given it is essential that an experienced anaesthetist should be in charge, as the room is often in darkness for seven or eight minutes. The legs are now raised by a nurse, and the cervix is caught with a bullet-forceps vulsellum, and the cervix and os are swabbed with a Playfair probe dipped in tincture of iodine. The nozzle is inserted into the cervical canal, and kept firmly in place by combined pull on the vulsellum and pressure on the syringe; this causes very little, if any, discomfort to the conscious patient. The legs are now placed flat again.

It is an advantage if the observer can adjust his eyes, by closing them, or wearing special spectacles for three minutes before the actual test, as the filling of the tubes will then be seen easily on the screen.

The lights are now turned out, the screen is placed on the patient's abdomen, and the current switched on. The nozzle and vulsellum will now be plainly seen. The piston is then screwed in so as to deliver 5 c.cm. of lipiodol, and the uterine cavity will at once become obvious as a triangle, apex downwards. This triangle is roughly equilateral if the uterus is in normal position, but becomes almost crescentic from foreshortening if the fundus is retroverted or anteverted. The injection is now slowly continued, while the pressure is watched carefully. There is usually a short delay before the tubes begin to fill; this is caused by the presence of the sphincters at the cornual ends of the tubes, described by Hueser and Bakke.[1] Then, in a normal case, the tubes will suddenly fill, and the lipiodol can easily be seen running out along them, and forming a small collection in the peritoneal cavity. If the tubes are obstructed this process may be seen to a greater or less degree on either side, or no lipiodol at all may enter the tubes. When it is suspected that the tubes are blocked the manometer must be watched with care. A conscious patient will complain of pain when the pressure is between 180 and 250 mm. Hg, and I do not think it safe to let the pressure rise above 250 mm. when the patient is anaesthetized.

In any case, as soon as the tubes are filled up, or as soon as the pressure reaches 250 mm., a radiogram is taken, and a second one when the maximum pressure has been reached. The patient is now turned on to her side (the nozzle still *in situ*),

FIG. 2.—The same two minutes later at 150 mm. Lipiodol passing into peritoneal cavity.

FIG. 3.—The same twenty-four hours later. Lipiodol well diffused; tubes empty.

and a lateral-view film is exposed. This last one is most important.

The procedure is now finished, and the patient rests for a short time, and can then go home. In no case have I heard any

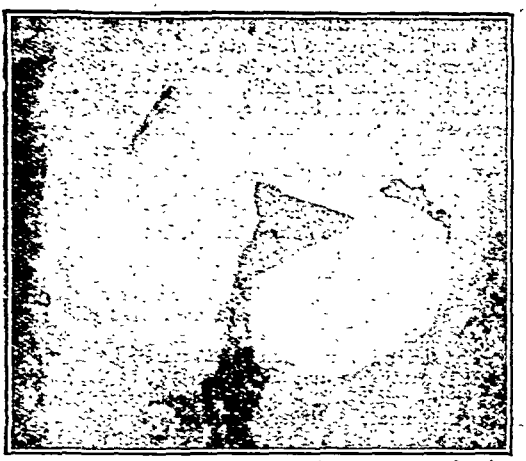

FIG. 4.—Obstruction at the fimbriated ends of both tubes. Lipiodol did not pass at 250 mm.

complaint of the typical pain caused by the CO_2 method when the patient stands up. After twenty-four hours another radiogram should be taken. It is surprising how, in some cases where the lipiodol did not seem to pass through the ends of the tube into the peritoneal cavity, it will be found there next day, and this "twenty-four-hour film" is a valuable check on negative results.

The radiographer needs considerable experience to produce the best results, and Dr. Mayes, the radiologist to the Bristol Royal Infirmary, tells me that high amperages are needed, the average exposure being about 1 to 2 seconds for front views and 3 to 5 seconds for lateral. A Potter-Bucky apparatus produces most beautiful *x*-ray films, but renders screening very difficult, unless specially made for this purpose, and I have found that the ordinary screening couch apparatus produces films quite good enough for ordinary diagnosis. The whole procedure does not take more than ten or twelve minutes, and is no great tax on

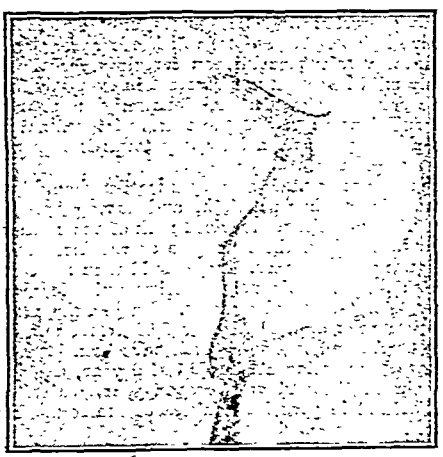

FIG. 5.—Fibroid; typical distortion of uterine cavity; obliteration of both tubes, stump of left tube showing.

the radiologist or gynaecologist, but I must extend my sympathy to the anaesthetist, if one is employed.

The advantages derived from this simple operation fall into two groups—diagnostic and curative. Although the injection of CO_2 is of the greatest value, I think anyone who has tried the lipiodol method will agree that it is very greatly superior, for the following reasons.

1. It will demonstrate the exact position of any tubal block, even if only one tube is obstructed, and in conditions of obstruction of both tubes the prognosis is entirely dependent on the site of the obstruction. Any operation for freeing the tubes is almost useless unless the obstruction lies at the

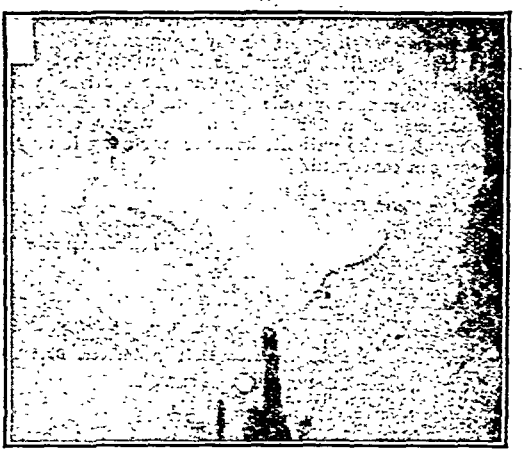

FIG. 6.—Uterus bicornis-unicollis; severe chronic salpingitis both sides, but lipiodol passed on the right. (Verified at operation.)

fimbrial ends, in which case the prognosis as to pregnancy is fairly good after operation.

2. It will demonstrate the fact that a uterus is not pregnant, a difficult question in the early months.

3. It will show the presence of interuterine growths, such as myomata or carcinomata, in cases of metrorrhagia with a big uterus, and so distinguish them from "fibrosis uteri."

4. It gives a very good idea as to the ease or otherwise of an intended myomectomy.

5. It will decide whether a pelvic tumour is of a gynaecological nature or not—for example, in a case of carcinoma of the colon which had become adherent to the fundus both tubes were normal.

With regard to its use in treatment, I feel sure that the heavy oily lipiodol is a better clearer of the so-called "sticky tubes" than is gas. In many of my cases the lipiodol did not pass until 180 or 200 mm. were registered, but the

FIG. 7.—Normal pregnancy showing the lipiodol lying round the sac and in the lower segment.

twenty-four-hour film showed complete emptying into the peritoneal cavity. In two cases gas insufflation had previously failed, but the tubes opened up to lipiodol. Jarcho[12] claims that the iodized oil is a most useful therapeutic agent, and quotes several authors to this effect; I have had no personal experience of this.

It would seem that in the lipiodol injection, when

properly controlled by *x ray*, we are possessed of an invaluable method of diagnosis in cases of sterility, far superior to any previous technique. Its only contraindications are septic cervicitis or pregnancy, and the latter is quite disregarded by Huesor,[11] but Béclère[1] advises against using this method of diagnosis owing to the bad effects of the x rays (not the lipiodol) on the pregnancy.

Apart from sterility, I think it is a useful, but by no means necessary, adjunct to diagnosis, for the reason that a pelvic tumour usually calls for operation, and the mistaken diagnosis of a fibroid for a parovarian cyst is of small moment to the patient, however annoying it may be to the surgeon concerned.

THE PRODUCTION OF IMMUNITY TO TUBERCULOSIS IN MAN AND ANIMALS.*

BY

NATHAN RAW, C.M.G., M.D., F.R.S.Ed.,

LORD CHANCELLOR'S VISITOR.

BEFORE discussing the problem of immunity to tuberculosis it will be necessary to consider very briefly some of the outstanding facts about this disease. Tuberculosis, unlike other infectious diseases, advances slowly and progressively, and though it may be arrested in its march at the lymph glands—the first natural barrier—only to become active again later, its progress, as in pulmonary tuberculosis, is more often continuous. It is probable that in addition to the human, bovine, and avian tubercle bacilli there are certain intermediate types, and that the human body may be attacked by a mixture of types. Each type of tubercle bacillus is selective and can live only in the host to which it has become accustomed for centuries.

From twenty-five years' experience of subculturing and growing tubercle bacilli, I am inclined to the opinion that the bovine bacillus is the original and true tubercle bacillus, and that the other types have evolved from long residence in different hosts. This view cannot be proved by investigations on animals, as they are generally not susceptible to infection by human bacilli. The human body is readily infected by both human and bovine bacilli; avian bacilli, which infect chicken and birds, do not infect the human subject. In the light of our present knowledge we cannot determine with certainty the exact origin of every infection of the human body by tubercle bacilli. Cytological differentiation between human and bovine bacilli is not possible; mankind, from its consumption of milk, butter, and cheese, has become so accustomed for centuries to infection from cattle that the bovine bacilli have adapted themselves to their new environment and grow well in human tissues; yet the human bacilli will not grow in the tissues of cattle.

In studying tuberculosis it is necessary to consider what may happen to an invading organism in a foreign host. Bovine bacilli introduced into the body of a child may, after a few years, undergo a modification of type; their virulence may be reduced and they may assume the characteristic properties of the human bacilli. Should such modification occur it would obviously be difficult by ordinary laboratory methods to determine with accuracy whether or not the bacilli belonged to the human or the bovine type. A child infected with bovine bacilli in infancy might possibly be certified ten or fifteen years later as suffering from a human infection, owing to the transmutation of the organism in human tissues.

In 1901 I published a paper in the *British Medical Journal* stating the following views. (1) That human and bovine infections produce separate and distinct diseases in the human body, and that they are antagonistic to each other. (2) That human bacilli cause primary pulmonary tuberculosis, while the bovine type cause enlarged glands, mesenteric disease, bone and joint lesions, etc. (3) That patients suffering from pulmonary tuberculosis rarely develop bone, joint, or gland lesions, and vice versa; in fact, that the human subject is protected by one infection against the other. (4) That cattle and pigs are immune against infection by the human bacilli, but that the human subject is susceptible to both. It was evident to me at that time that it would only be possible to immunize animals by using human bacilli. A series of animals were tested in this way, but the bacilli used were too virulent and every animal was killed.

In 1906 I decided to attempt attenuation of bacilli by repeated subculturing and thus reduce their virulence and lower their toxicity. The only certain method of permanently attenuating virulent cultures of tubercle bacilli is by long-continued and systematic subculturing spread over a number of years. For this purpose I used a pure culture on glycerin agar of human bacilli from a virulent case of pulmonary tuberculosis, a virulent bovine culture from the mesenteric glands of a cow, and a culture of avian bacilli from the liver of a chicken. These cultures have been grown on glycerin potato and transferred to glycerin agar every month for twenty-two years, the present growths representing the two hundred and sixtieth generation. The growths are still profuse and true to type, but they are now completely non-pathogenic to animals. Every year since 1906 I injected these bacilli into animals, and until the year 1913—that is, until the eighty-fourth generation of subcultures—I observed no change in their virulence. After that time attenuation became marked, and in a series of animal inoculations carried out in 1914 the subcultures were observed to be avirulent.

A further series of animals was inoculated a year ago with a protective vaccine prepared from attenuated cultures of human bacilli, and these animals, together with unprotected controls, were given each half a milligram of virulent bovine bacilli. All the unprotected animals rapidly developed general tuberculosis and died within four months, while the protected animals showed only local and non-progressive lesions. An animal which can resist the laboratory dose of virulent bacilli can certainly resist the comparatively mild infection it may meet in everyday life. If, then, we can produce artificial immunity in man and in animals sufficient to enable them to resist ordinary infection we shall have gone a long way towards stamping out tuberculous infection.

Calves that are to undergo immunization should be separated from the mother at birth, and having been fed on healthy milk or on the pasteurized milk of the mother for a week should be given the first dose of vaccine, the second dose following a week later. They should then associate with the other animals. This method of immunization is applicable only to non-infected animals. During the past three years it has been applied to over 2,000 calves in valuable pedigree herds, and careful records have been kept. These calves have been tested at the end of a year, and in many cases again at the end of a second year, with Pasteur's tuberculin, and in practically all cases the result has been negative.

The production of immunity in the human subject is complicated by the fact that children are susceptible both to human and to bovine infection. A year ago, at the request of their parents, I inoculated all the children—about one hundred—living in a large tuberculosis colony, where all the male parents were suffering from pulmonary tuberculosis, with two doses of protective vaccine prepared from bovine bacilli. So far these children appear to be quite healthy, and though it will require years of observation before we can form any opinion as to the efficiency of the vaccine, I believe that in time it will be possible to

* Summary of paper read before the Liverpool Medical Institution, March 21st, 1929.

immunize children, especially those who are directly exposed, against tuberculous infection.

Since 1902 tuberculin has fallen into disrepute, but I have no doubt that it will come into its own again, and that preparations from non-virulent attenuated cultures which produce no reactions will be recognized to be of the greatest service in the treatment and prevention of all forms of tuberculosis. Attenuated cultures retain the quality of producing tuberculin, and, being deprived of their virulence and toxicity, are perfectly safe in use. A very small amount of vaccine prepared from such cultures is sufficient to protect a person from infection. Professor Calmette, in his prophylactic treatment of infants a few days after birth, uses a living attenuated culture of bovine bacilli to produce immunity against human infection. It is still too early to estimate correctly the results of his work, but there is a fundamental objection to using a living bacillus, as we do not know whether or not it may be reactivated after long residence in the human host.

In my view, all cases of tuberculosis should be treated by some form of tuberculin, which is the natural specific remedy; but this tuberculin should be prepared from attenuated, avirulent, non-toxic cultures. Pulmonary tuberculosis should be treated with tuberculin prepared from bovine cultures, and surgical tuberculosis with tuberculin from human cultures. Given in early cases of pulmonary tuberculosis tuberculin seems to limit the spread of the infection and to enable the patient to resist the disease. In no case can its administration do the least harm, and given scientifically it has often produced wonderful results. I have treated a large number of cases in this way, and have never seen any untoward effects. The best results are only seen in early cases. The method of stamping out tuberculosis is to immunize children of tuberculous parents and to produce active immunity in early cases of tuberculous infection.

MEDICAL, SURGICAL, OBSTETRICAL.

CALCANEAL SPURS OF TRAUMATIC ORIGIN.

IT is suggested in the lecture of Professor Fraser, in the issue of March 2nd (p. 383), that calcaneal spurs are the result of a trauma. On the other hand, Mr. A. H. Tubby, in his contribution on deformities in the *Encyclopaedia Medica* (second edition, vol. iii, p. 380), states that the general conditions associated are gonorrhoea, subacute gout, rheumatism, arthritis deformans, excessive standing, and, rarely, epiphysitis, tuberculous and syphilitic, of the os calcis. The two cases described below were recipients of compensation, and the questions to be decided in arbitrations under the Workmen's Compensation Acts were what final settlements were to be awarded.

The first case was that of a stevedore, who was working, on October 20th, 1925, in the hold of a lighter receiving sets of timber. A set which was being lowered got out of hand, and crushed his left ankle and foot against timber already in the hold. Swelling and pain were caused, and he ceased work. Subsequently he tried to do light work, but had to knock off owing to pain. He was examined on July 23rd, 1926, when the case came up on arbitration. Slight pain was complained of on extreme flexion of the left ankle, and some tenderness on pressing the middle of the left heel. Applicant was slightly lame, and, with his heel on the ground taking the weight of his body (13 st.), everted the foot. X rays showed on the left os calcis a small spur, situated on the fore part of the inferior surface, not on the most dependent part. There was also a second spur at the insertion of the tendo Achillis. The onus was on the applicant to prove that the condition was due to injury arising out of, and in the course of, his employment, but the case was settled on payment of £275 and costs offered by the respondent.

In the second case a workman who fell from a height of 11 feet badly bruised his heels, and was said to have fractured both calcanea. This accident occurred early in 1925. X rays showed enlargement of these bones, opacities, spurs on the inferior surface, and thick spurs at the insertion of both the tendines Achillis. The effect was to produce pain on standing and inability to work. A final settlement of £425 and costs was made on March 8th, 1928.

It would appear that these cases drag on, compensation being paid all the time; medical men advising those concerned would be justified in suggesting an early settlement, since otherwise the mental element comes in, and it is difficult, even after treatment similar to that recommended by Professor Fraser, to get the workman to return to full work. Both patients were middle-aged men, and no signs of rheumatism or arthritis could be found.

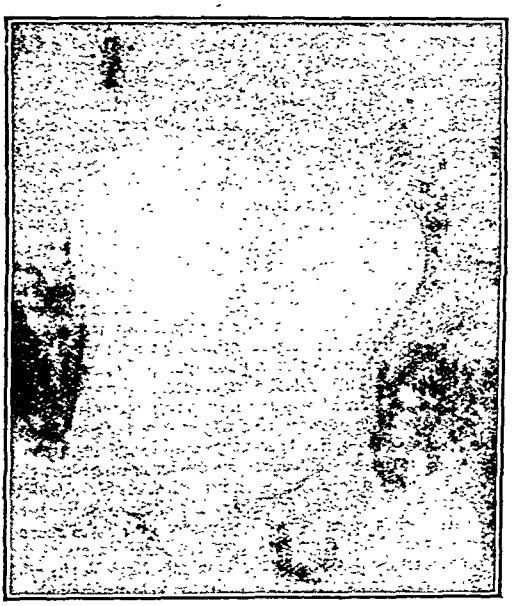
FIBRO-SARCOMA OF ISCHIUM TREATED WITH RADIUM.

THE following case seems worth recording, not only on account of its rarity in such a position and the success attending treatment, but on account of the history.

A healthy boy of 15 was sent to me in April, 1926, by Dr. V. Ll. Jones of St. Clears, with a somewhat tender swelling about the size of a small walnut connected with bone in the right perineum at or behind the junction of the pubic and ischial rami.

The history was that of a so-called chill in the previous December, with pains in the lower limbs, for which he stayed in bed two or three days. On getting up he suffered from acute pain in the right perineum and inner side of the right thigh, for which he was kept in bed a further three or four days. After



this he continued to get the same pain, though less severely, on walking or running. The swelling could be distinctly felt per rectum, though not so pronounced as through the perineum. X-ray examination showed the bone to be expanded in cyst-like form. He walked with a limp, there was some atrophy of the thigh muscles, the movements of the hip were free, and jarring on the heel caused pain in the right perineum. The diagnosis was cyst of bone or chronic abscess.

On April 19th the swelling was exposed by incision, the shell of bone broken into, and the contents, evidently new growth of tough consistence, removed with a sharp spoon. The wound was closed round a small drainage tube, the deep end of which occupied the cavity. The growth was examined by Dr. A. F. Sladden, director of the Beck Laboratory, Swansea Hospital, who reported that sections showed "mainly organized fibrous tissue with areas of fibro-sarcoma, specially in relation to bony tissue; order of malignancy low."

On April 22nd 25 mg. of radium screened by 5 mm. of silver were introduced along the track of the tube into the bony cavity and left for twenty-four hours.

The boy has enjoyed perfect health since. Nothing is now felt per rectum, and only some slight irregularity of bone in the perineum.

From the way in which the bone had been expanded the growth must have been of considerably longer duration than three months, and at first certainly benign in character. It would seem that at the time of the onset of the symptoms the sarcomatous elements had suddenly begun to assert themselves, and by growth caused increased tension in the bone cavity, with pain and lameness.

The patient and the microscopic specimen were shown at a clinical meeting of the South Wales and Monmouthshire Branch of the British Medical Association at Swansea on February 7th last.

Reports of Societies.

SURGERY AND RADIUM IN CARCINOMA OF THE CERVIX.

AT a meeting of the Section of Obstetrics and Gynaecology of the Royal Society of Medicine on May 17th, with Dr. J. S. FAIRBAIRN in the chair, Mr. VICTOR BONNEY opened a discussion on the results of surgery compared with the results of radium in carcinoma of the cervix. The discussion was really a continuation of the one which took place at the recent visit of Professor Heyman to the society (*British Medical Journal*, March 9th, p. 449).

Mr. Victor Bonney said that up to the end of 1923 he had performed Wertheim's operation for carcinoma of the cervix on 265 patients out of 420 seen. There were 105 five-year survivals, so that his relative cure rate was 39.6 per cent., and his absolute cure rate 25 per cent. These figures would be higher had he not reckoned as dead of cancer 21 cases lost sight of or dying of other diseases within the five-year period. Of the 265 patients operated on, the regional glands removed were carcinomatous in 113—a gland-involvement rate of 42 per cent. Of those whose glands were involved, 27 survived operation for at least five years; of the 152 without carcinomatous glands, 78 survived. After pointing out that radium applied to the vagina did not reach out to the regional glands, he stated that out of every hundred unselected patients presenting themselves at a radium clinic, roughly forty were beyond the scope of radium, having carcinomatous glands. About the same proportion of those presenting themselves at a surgical clinic were beyond the scope of surgery on account of gross extension of the growth to parts operatively irremovable. The two groups of forty were not, of course, identical; the surgeon, however, could distinguish his 40 per cent. of inoperable cases by an exploratory opening of the abdomen, whereas the radiologist could not detect his refractory cases beforehand. Mr. Bonney then contrasted his own five-year results in surgery with those of Heyman, from the Radiumhemmet, Stockholm, and of Gray Ward, from the Women's Hospital, New York, which were the most favourable to radium yet published. To the objection that a larger proportion of patients with advanced disease were sent to radium than to surgical clinics, Mr. Bonney answered that this weighed not at all in communities where operation had been entirely superseded by radium, for the cases there presented for radium treatment were as representative of the cases in the community at large as those attending a gynaecological clinic. The cases *in extremis* in Heyman's and Gray Ward's series were in no larger proportion than those which came the way of the gynaecologist. The comparative figures were as follows:

	No. of Cases Seen.	No. of Cases Treated.	Five-year Survivals.	Absolute Cure Rate (per cent.).	Relative Cure Rate (per cent.).
Bonney ...	420	265*	105	25.0	39.6
Heyman ...	467	444†	106	22.7	23.8
Gray Ward ...	138	131†	31	22.4	23.1

* Operated. † Radiated.

This comparison was not fair to radium, because while only 63 per cent. of his own patients had been operated on, 95 per cent. of the others had been radiated, and it was obvious that the cure rate would be higher the smaller the percentage of cases treated. A fair comparison was obtained by contrasting the results in his group of gland-free cases operated on (representing a selection of 36 per cent. from all the cases he had seen) with the results Heyman and Gray Ward had obtained in certain clinical groups of cases in which the growth was limited to or had only slightly passed beyond the cervix. The number of gland-free cases on which he had operated was 162, and the number of growth-limited cases radiated by Heyman was 186, and by Gray Ward 32. The five-year survivals for the three workers respectively were 78, 76, and 17. Again, while sixty-three out of every hundred presented to him were operated on, sixty out of every hundred presented to the radium workers were within the scope of radium treatment, their glands being uninvolved at the time. The results, therefore, might be set out in another table.

	No of Cas. s Seen.	Cases within Scope.	Percentage of Total Cases.	Five-year Survivals.	Percentage of Cures.
Bonney ...	420	265	63	105	39.6
Heyman ...	467	280	60	106	37.8
Gray Ward ...	138	82	60	31	37.7

If there were no such thing as glandular involvement radium would give better results than surgery. It was in the gland-involved cases that surgery attained its numerical superiority in absolute cure rate over radium. His own figures for the 40 per cent. of gland-involved cases showed a cure rate of 16 per cent., whereas with the two radium workers in this category of cases the cure rate was *nil*. These facts and considerations, Mr. Bonney maintained, showed that his results with Wertheim's operation were numerically better than those obtained by radium. Moreover, owing to the facilities enjoyed by the Radiumhemmet, none of Heyman's patients had been lost sight of, whereas he had lost sight of thirteen patients, all of whom were counted for the purposes of this comparison as having died of recurrence. His figures also included patients operated on many years ago, when his operative mortality rate was 20 per cent., instead of 11 per cent. as in his last hundred cases. He had kept no record of the cases abandoned as inoperable. Had it been possible to have treated some of the earlier ones by radium as they would be treated now, a certain proportion would have been cured. If allowance were made for these considerations, he thought the results of his total cases would be far superior to anything afforded up to the present by radium treatment alone. He had confined himself in these estimations to the results of operation on the one hand and of radium applied from the vagina on the other. No evidence was yet available as to the results capable of being attained by radium applied through the abdomen as well as through the vagina, or of radium applied through the vagina in combination with operative extirpation of the regional glands. At the present time, in spite of the improved results of radium treatment, a greater number of lives would be saved by subjecting to operation all patients whose growths were removable by an expert in this branch of surgery, and treating the remainder by radium, than by using radium to the exclusion of surgery.

Dr. J. S. FAIRBAIRN said that he was glad that Mr. Victor Bonney had made out such a good case for surgery, because at the present moment there was a danger of the pendulum swinging too violently to the radium side.

Mr. SIDNEY FORSDIKE considered Mr. Bonney's figures to be remarkable as showing the state of treatment of cancer of the cervix, but asked whether he remained content with a 25 per cent. cure rate for all cases. He thought that Mr. Bonney had put his finger on the weakness of the Stockholm method when he pointed to the number of cases with gland involvement which remained

uncured. The speaker had treated a number of cases on the Stockholm plan, and the majority of the advanced cases never cleared up from the vagina at all; the ulcer would heal, but the growth was still present in the vaginal vault. In about 30 per cent. of the cases, at the end of three or four months, nothing could be observed but a thickening in the roof of the vagina, the nature of which was not clear. In this class of case the majority of recurrences were high up in the pelvis, which the Stockholm method could not attack. He thought Heyman's method must necessarily fail unless some different strategy were adopted.

Dr. A. J. WRIGLEY gave some figures showing the operation results in carcinoma of the cervix in 148 cases admitted to hospital for treatment between 1918 and 1922. Of this number 18 per cent. were considered operable, 20 per cent. borderline, and 60 per cent. inoperable. Trace was lost of only seven of the cases. The absolute five-year cure rate on the 148 cases was 15 per cent. Of the operable cases 60 per cent. were alive at the end of five years, and just under 30 per cent. of the borderline cases. The cases were treated in two ways, either by Wertheim's hysterectomy or by total hysterectomy with application of radium to the operation site in the pelvis. He mentioned the large number of the borderline cases which died in the second or third year.

Dr. HERBERT SPENCER mentioned that Döderlein recently gave particulars of 1,443 cases treated by radium and x rays, with an absolute cure rate of 15.4 per cent.

Mr. MALCOLM DONALDSON said that last year at the Cancer Congress he had ventured to say that it was a difficult matter to compare the results of radium and of operation. Mr. Victor Bonney had replied that it was very easy; but what he had shown that evening had convinced him (Mr. Donaldson) that he was right in claiming that it was difficult. Mr. Bonney assumed that the cases sent to a radiological clinic like that of Stockholm were the same as the cases now sent to surgical clinics. That was a very big assumption to make. He could not but believe that where Mr. Bonney was there would be a very high percentage of early cases sent in order that Wertheim's operation might be performed. The results with operation and with radium approximated so closely that it seemed to him that radium treatment, which was at present only in its infancy, ought to be followed. He believed that the figures would be very much better in the course of the next five years.

Mr. W. GILLIATT said that since 1923 he had dealt with carcinoma of the cervix by treating all cases, both operable and inoperable, with radium, and submitting the operable to a Wertheim's hysterectomy between four and six weeks afterwards. The total number of cases was very small; he had performed Wertheim's hysterectomy on thirty-two occasions after the use of radium. He thought there was very little doubt that the cases on which it was possible to operate did better after the preliminary use of radium; the effect of the radium was to cause an atrophy of the growth. Of the thirty-two cases mentioned, one died of operation, seven of recurrence, one could not be traced, and the remainder were alive and well. In addition to these, he had to abandon the operation in eight cases on account of involvement of parts operatively irremovable.

Mr. DUNCAN FITZWILLIAMS thought that Mr. Bonney's figures had proved that radium did almost as well as surgery, and radium was in its infancy. The results of radium treatment in future years, proceeding from the basis of the results obtained to-day, would outstrip those of surgery. Radium must go ahead, but he thought it unfortunate that the three centres of radium in Europe—Copenhagen, Brussels, and Paris—or at least the latter two, which he had visited, were becoming extraordinarily stereotyped. More radium centres were wanted—at least ten or fifteen—and advance would then be rapid.

Mr. VICTOR BONNEY, in reply, said that he had tried to put the case for radium and surgery as fairly as possible. He was certainly not content with an absolute cure rate of 25 per cent. He described carefully, in answer to a question by Dr. Herbert Spencer, how he arrived at his operability rate of 63 per cent. He gave reasons for believing it difficult for anybody to operate on more than 63 per cent. of the cases seen. With regard to radium, he felt that the wave of enthusiasm passing over the country at the present time was a very foolish thing, and bound to end in disappointment. Finally, he quoted some operation figures which had been given him by Mr. Fletcher Shaw: 106 operations, with 23 deaths due to operation (a mortality of 21 per cent.), 35 recurrences in less than five years, and 40 five-year survivals.

Contraindications to Radium Treatment.

Dr. GILBERT I. STRACHAN (Cardiff), at the same meeting, read a short paper setting out some contraindications to radium treatment. In a number of centres, he said, radium was now used in preference to radical removal, and many striking cases were cited in which advanced growths of the cervix were treated by this means. It was desirable, therefore, to indicate the conditions which rendered radium unsuitable, or even dangerous. In an extreme degree of general emaciation and cachexia radium was likely to produce rapid deterioration and early death; radium treatment should be postponed until the general condition improved, if it was going to improve. Extreme anaemia, repeated or severe haemorrhages, or toxic absorption from a foul cervix were contraindications. There was a tendency for radium itself to produce a certain degree of anaemia, and this, added to a previously existing anaemia, might reduce the blood count to a dangerously low level. Other contraindications might be classified under the heading of extension and metastases. The presence of a fistula into the bladder or rectum was an absolute contraindication, also the presence of any inflammatory pelvic lesion, or a foul and sloughing condition of the growth. The presence of salpingitis, pyosalpinx, or inflammatory abscess was a contraindication, owing to the likelihood of peritonitis being set up. If there was evidence of impaired metabolism, and especially of defective excretion of nitrogenous waste products, radium should be withheld. The indiscriminate application of radium in cases exhibiting some of these contraindications had led in certain cases to unfortunate or even disastrous results. One unhappy result of the great amount of attention given to radium as a cure for cancer might be that men without qualification or experience would attempt to apply radium in unsuitable cases, with disappointment to themselves and detriment to their patients.

Dr. FAIRBAIRN believed general cachexia to be a very important contraindication.

Mr. MALCOLM DONALDSON thought the warning given in the paper was very timely. The wave of enthusiasm for radium which was spreading over the country made it likely that people would expect too much, and in the reaction radium would be undeservedly condemned.

Dr. EDGAR HAYDON (Newton Abbot) said that much was written about the beneficial effect of radium without consideration being given to the serious conditions under which the radiologist employed it. In a large number of cases, especially where there was considerable sloughing of the cervix, it was impossible to find the canal until a small dose of radium had been used on the surface. The danger of salpingitis had not been overestimated; indeed, to overestimate it would be difficult. He himself had been using radium in a small hospital for fourteen or fifteen years. The benefits derived from it were very great, and the dangers, on the whole, were overestimated.

A Straight-rod Pelvimeter.

Dr. HERBERT SPENCER exhibited a new pelvimeter, a model of which he had presented to the obstetric unit of University College Hospital. It consisted of a straight steel rod, pointed at one end and rounded at the other, with two uprights having movable slides so as to enable the positions of the rod to be indicated on a sheet of paper. By joining up the dots obtained corresponding to the pubic and sacral promontories, in a manner he illustrated, it was possible to measure the true conjugate.

THE ACTION AND USE OF EPHEDRINE.

At the meeting of the Section of Therapeutics and Pharmacology of the Royal Society of Medicine, on May 14th, a discussion took place on the action and use of ephedrine.

Constitution and Physiological Action.

Professor J. A. GUNN, president of the Section, reminded the meeting that ephedrine was an alkaloid obtained from the plant *Ephedra vulgaris*, decoctions of which had been used in ancient times by the Chinese as a circulatory stimulant and diaphoretic. The alkaloid was isolated in 1887, but did not attract very much attention for a long time until, perhaps five or six years ago, its constitution was disclosed and the resemblance of its chemical structure to adrenaline was noted. There were two varieties of ephedrine, the original alkaloid and pseudo-ephedrine, an alkaloid isomeric with the first; this explained a good deal of the confusion which had arisen with regard to the action of the drug.

Dr. J. H. THOMPSON, who had been investigating the action of ephedrine on normal human subjects, said that so far his results were incomplete, but a few interesting facts had emerged. He had found, in the first place, that there were a considerable number of people who failed to respond to ephedrine. This could not be put down to inactivity of any of the samples of ephedrine used. He had made oral, subcutaneous, and intramuscular administrations in the same individuals, with no response so far as alteration of blood pressure was concerned. He could not find anything abnormal about these people, except that there was definite evidence of failure of full development of secondary male characteristics. In other persons subjected to the investigation he noticed a definite latent period before the rise in blood pressure which normally took place. On subcutaneous or intramuscular injection, this latent period was from 2½ to 3 minutes, and on oral administration, from 7 to 10 minutes. During this latent period the blood pressure often exhibited an initial fall, quite irrespective of the mode of administration. The rise of blood pressure which succeeded was very much greater if the administration was by injection than if it was by mouth. The oral effect, less marked though it was, was increased if the ephedrine was given on an empty stomach. The eventual rise of blood pressure in these cases was somewhat striking. It had been freely stated that after the injection of ephedrine the blood pressure for a considerable period was well maintained, but the experiments which the speaker had made contradicted that view. There was, first of all, well-marked rise of blood pressure which persisted only for a few minutes (7 or 8), and then there was a return to normal blood pressure. This was succeeded by a second rise, and it might be there were five or six such rises of blood pressure occurring over a period of one hour to one hour and a quarter. If the drug was administered intramuscularly or subcutaneously, the rise of blood pressure was greater, and the rises more rapid than with the oral method, though not so many rises occurred. Another interesting factor was that the blood pressure, after a series of rises, fell below the normal—that is to say, there was a marked after-fall. In one experiment the blood pressure was maintained at the low level of 109 for forty minutes, and an hour later it had risen only to 117—a very slow recovery. These facts—namely, that there was a tendency to an initial fall, and always a definite after-fall—would indicate the need for some caution in the administration of ephedrine. Another interesting fact was the form of the rise, which frequently exhibited a step or dip in the curve, such as was obtained from stimulation of the splanchnic nerve; he was unable to state the significance of this.

In Relief of Asthma.

Mr. FRANK COKE said that, for better or worse, the use of ephedrine had spread throughout the world of asthma in a very few years. The real treatment of asthma, of course, consisted in the discovery of the cause and its removal or neutralization, but anyone who saw an asthmatic in full distress was naturally pleased to have any drug which would do some immediate good. The particular type of case in which he had used this drug had been that in which the attacks were occasional, although perhaps fairly severe. Such attacks, though occurring after long intervals, were dreaded by the patient, and might come at very inconvenient times. The knowledge that this drug was available was a great relief to the patient. A young naval lieutenant had infrequent but severe attacks of asthma; he kept a tube of ephedrine in his pocket, and it restored his confidence and perhaps averted an attack when the time was singularly inconvenient. There was, of course, a danger in these easy methods of administration, but he had always looked upon the asthmatic as a very sensible person, and not likely to form drug habits. Ephedrine had advantages over adrenaline, one of the chief being that it was given by the mouth and not only by the hypodermic syringe. Another great advantage was that it extended the immunity from attack, which with adrenaline was for a period of two or three hours, to double that time, so that it was possible for the victim to carry out a business engagement or have an evening's entertainment. According to some observers, ephedrine had an extraordinary effect on the nasal mucous membrane. This was a thing which could be watched, and the effect of the administration of ephedrine, either by the mouth or by painting it on the mucous membrane, was to reduce the turgescence of the membrane. The disadvantage of ephedrine was that in certain patients, after full administration, there might be tremor, palpitation, and insomnia, though he had not noticed this last himself. It had been used as an antidote for morphine and scopolamine. A peculiar symptom had been noticed by some American observers after the injection of ephedrine hypodermically—namely, agonizing pain in the head, in the suboccipital region. He had noticed the same thing one or twice with adrenaline. There was much mention in literature of diuresis following ephedrine. This, however, was very common in attacks of asthma, so that he would not attach great value to it. A far more frightening thing was inability to micturate at all. The patients sometimes felt no urge to micturate, and any attempts to do so were entirely futile. With this drug one would seem to get a paralysis not only of the bronchial and the intestinal muscles, but of the bladder also. Asthmatics were, of course, extraordinary people, and there might be something in the nature of idiosyncrasy to the drug. He urged that the chemists should make up quarter-grain instead of half-grain tablets, or that resort should be had to the liquid form, which would enable the minimum dose to be given.

Dr. JOHN FREEMAN started using ephedrine about three years ago, and tried it on difficult asthmatic cases. After a time he gave it up. His experience was that at first it seemed to do a great deal of good, but afterwards one was not quite so sure that it was doing any good at all. For about two years he did not use it, and then, quite lately, he had started it again, and had used it on several cases, getting much the same results as before. The first dose seemed to act marvellously; subsequent doses did little or nothing. He recalled one case in particular—that of a very asthmatic woman, who was put on half a grain a day. At first the result was proclaimed by the nurse as splendid, but after a day or two she was less sure. Then it was decided to give ephedrine one day and a dose of normal saline the next day. There did not appear to be any distinction between the effects. The ephedrine was then given on one day and the salt solution on two succeeding days, still with the same result, until now the patient was having ephedrine one day a week, and on the other days normal saline, and no difference was perceptible. With asthmatic patients, of course, if the doctor or nurse was excited about any new treatment, the excitement was readily communicated to the patient, with perhaps deceptive results. Thus the first effects of any new therapy had to be discounted.

Uses in Obstetrics and Gynaecology.

Dr. J. H. HANNAN mentioned the use of ephedrine in gynaecology and obstetrics. Obstetric shock and collapse were almost invariably associated with considerable loss of blood. He had given ephedrine in these cases—1 grain in

8 c.cm. of normal saline intravenously—and had been able to get the patient into a satisfactory condition. He had on occasion given 2 grains of ephedrine with no ill effect. He had also found it useful in obstetric shock in the newborn. In gynaecological cases he had as a routine given 1 grain of ephedrine one or two hours before any operative procedure in which shock might be anticipated. With regard to the use of ephedrine in women at the menopause, he had shown that women at that period, while strangely sensitive to adrenaline, were very tolerant to ephedrine.

Professor GUNN mentioned that one of the great claims for ephedrine was that it was far less readily oxidized than adrenaline. The fact that it was not readily oxidized was supposed to explain why it acted by the mouth. With regard to tolerance, adrenaline produced tolerance, and the same thing had been shown both in animals and man with ephedrine, but apparently the tolerance was produced more quickly with ephedrine than with adrenaline. Ephedrine had been used in shock in a variety of conditions—largely, in America, to avert the shock in spinal anaesthesia. Insomnia was evidently quite a characteristic effect with ephedrine. Sweating apparently occurred only with very large doses. Profuse sweating was a sign that the dose given was too large. He thought that no deaths with ephedrine had been recorded, but there were some quite serious collapse cases.

Dr. J. H. HANNAN mentioned three cases in which toxic effects were seen; one of them showed slight bladder irritation with a dose of 1½ grains three times a day, the other two simply complained of perspiration. These were the only symptoms of overdose that he had had. The general statement of the patient testified to a sense of well-being, of definitely increased strength and vigour—a kind of euphoria. This lasted only for the hour or so during which the blood-pressure rose.

Dr. PHILIP HAMILL asked whether anyone had reported discomfort after the administration of ephedrine by the mouth. On making observations on animals one found that the auriculo-ventricular interval was shortened. After giving a fairly large dose of strophanthin in an isolated heart, the addition of a small quantity of ephedrine would cut down the prolongation of the interval by one-half, bringing it back to what it was before strophanthin was given. With regard to its use in asthma, he knew one asthmatic lady who was always compelled to carry with her half a dozen handkerchiefs, but as a result of ephedrine now carried only one. With a quarter-grain dose she had not developed tolerance. He had noticed in one case of exhaustion with low blood pressure a definite slight improvement lasting some little time after ephedrine—whether the result of suggestion or not he could not say.

Dr. J. H. THOMPSON said that in decerebrate animals small doses of ephedrine—about 0.15 grain—repeatedly given produced a fall in blood pressure without any subsequent rise. These falls might eventually become so profound that the circulation failed to recover and the animal died. In human subjects, when the dose had been repeated, what he had described as the after-fall was very much greater—the fall following the previous rise was almost precipitous.

Dr. GEORGE GRAHAM had seen two colleagues who had suffered from hay fever, and had considerably benefited by the use of ephedrine. One of them had been in America, where he was extensively inoculated against hay fever without benefit. He took a grain of ephedrine twice a day, and was very much better. Possibly for hay fever the drug might have a big future.

Dr. E. P. POULTON recalled one very bad case of asthma which was untouched by ephedrine. But fairly recently he had seen an Austrian physician who had a very bad attack of asthma as soon as he landed in this country. This man had some ephedrine with him, and "swore by it." Since then the speaker had seen other cases which gave favourable results. He thought it was in the occasional attack that it was of benefit, not in attacks which came on night after night.

Professor GUNN said that he had been interested in the statement with regard to euphoria, especially in view of the fact that ephedrine was employed to remove the morphine habit.

"ANTIVIRUS" THERAPY.

AT the annual general meeting of the Section of Tropical Diseases and Parasitology of the Royal Society of Medicine, held at the Society's House on May 15th, with Dr. J. B. CHRISTOPHERSON, the president, in the chair, a paper by Professor A. BESREDKA of the Pasteur Institute was presented, on antivirus therapy in infectious diseases. Owing to influenza, Professor Besredka was unable to attend, but his paper was read in his absence. The following is a summary of his argument.

The name "antivirus" was given to substances of microbic origin capable of local vaccination without the introduction of antibodies. Like the organism from which they were derived, the antiviruses were selective in their action, and affected only certain cells, called receptives; thus staphylococcus vaccine had an affinity for the cells of skin and mucous membrane, cholera antivirus for the lining membrane of the intestine, and so on. The antivirus had an immediate action, and was confined to cells with which it came into contact. As a direct result of absorbing the antivirus, these cells became impervious to the action of corresponding organisms. It might, however, also give rise to a general immunity, as in typhoid and anthrax. In the former, as soon as the intestine became refractory, the whole body might be said to be refractory also, since the other organs were not subject to typhoid. In anthrax, in guinea-pigs, the organism had an exclusive affinity for the skin; once saturated with antivirus, bacteria might be inoculated into any organ. Local vaccine treatment of the intestine at first met with considerable opposition, and it was not until the necessity for a sensitizing agent, such as bile, was realized in such diseases as typhoid and cholera (although not in dysentery) that the idea was accepted. During the past decade there were many publications to show that oral vaccination against dysentery had notably reduced both the morbidity and mortality of the disease, for both preventive and curative purposes. The effect of oral vaccination upon the development of an attack of dysentery was at least as beneficial as that of a subcutaneous injection of the specific serum. Oral antityphoid vaccination was now taking its place in ordinary practice, and was quite as effective as subcutaneous inoculation. This method was also used in cases where the disease had already manifested itself in order to prevent the gradual spread of the bacillus to the healthy cells of the intestine. Oral vaccines had similarly been tried in cholera epidemics, using bile as a sensitizing agent, and reports were favourable. It was certain that *B. coli* often played an important part in entero-colitis, and a close analogy existed between coli infections and typhoid and cholera. Zlatogoroff prepared a combined vaccine, containing the dysentery bacilli, *B. proteus*, and *B. coli*, called pentavaccine. Its use in man had been promising, both in prevention and in cure, and administration of vaccine by the mouth was being more and more commonly prescribed in serious cases of colitis. Urinary infections could not be considered wholly apart from colitis, and the commonest organism in the urine was *B. coli*, although other intestinal organisms were also found. Clinical results had justified the use of oral vaccines in this case also, although only some cases yielded to this treatment. In pyelonephritis, cystitis, and pyelitis local application of vaccine had given successful results.

Turning to a consideration of the eye, Professor Besredka remarked that this had little or no part in a general infection, and was only mildly affected by the development of general immunity. Various ocular affections in man had been treated by vaccine therapy. In blepharitis antivirus had been very successful, either by simple instillation or as an ointment. Similarly, in dacryocystitis, local vaccine therapy had given good results. The local use of antivirus in ear diseases had been equally successful. Furunculosis had reacted with astonishing effects to the application of antivirus: pain disappeared, and the boil rapidly healed. Other ear conditions had been treated in a similar manner, as also had nasal infections and suppurations of the sinuses. The local application of vaccine to the laryngo-pharynx had been the subject of numerous experiments and clinical observations, and it was possible that local vaccine therapy might some day be applied to the lung

itself. There were various oral conditions which manifested themselves in frequent suppuration and pain which could be successfully treated with local vaccine therapy applied by means of compresses. In pyorrhœa alveolaris the local application of antivirus produced a complete disappearance of pain, a return of the gums to normal, and a tightening of the teeth, but it alone did not cure the condition. The method had also been used in gynæcological affections which were due to local infections; antiseptics could be usefully replaced by antivirus, and many examples of this use were adduced. The pyogenic infections of the skin could also benefit from local vaccine treatment, and boils and carbuncles had been successfully treated. There were two methods in common use—intracutaneous injections and cutaneous dressings—the latter being the more commonly employed. Erysipelas had been favourably treated by a similar application of a streptococcal antivirus applied as a cream or a liquid, while soft chancres and buboes had been likewise improved, using an antivirus from Ducrey's bacillus. Professor Besredka concluded by observing that antivirus therapy was being more and more employed in surgical cases. Its uses in veterinary practice were as varied as in human medicine, and the application of anti-vaccination in anthrax in animals—the starting-point of all antivirus therapy—was to-day universally adopted as part of the ordinary routine of farming.

In the discussion which followed the reading of Professor Besredka's paper there was a general feeling that it was unfortunate that the exact nature of "antivirus" had not been fully described or the technical details of its preparation explained.

Major-General HARVEY pointed out that the army had conducted a considerable amount of research into similar methods. It had been tried for gonorrhœa, for example. At first, old filtered or centrifuged cultures had been instilled into the urethra, but this method had been discarded as too toxic. Later young cultures had been used, and finally these had been given intradermally. Twenty years ago they had tried it against typhoid. Glycerin-killed cultures were swallowed, but with very irregular results so far as antibody production was concerned. The oral dysentery vaccine had been used in the Shanghai force, and in two years only 76 out of 9,000 had developed the disease during the season. These results could not be regarded as conclusive, however, as there were no controls. There were, however, 400 cases of enteritis. Some of these might be mild cases of dysentery; on the other hand, if they were not, it suggested that the oral dysentery vaccine might be specific.

Mr. A. FLEMING believed that the antivirus was equivalent to the inhibitory substances found in exhausted cultures. He had grown moulds on broth for a week to ten days, and found that the filtrate had a greater inhibitory effect than antivirus on the growth of the pyogenic cocci. The results of its application to suppurative conditions were favourable, although it was not a specific effect.

Professor LEDINGHAM considered that, while oral anti-typhoid vaccination was effective, it was not more so than the normal method.

GASTRO-INTESTINAL INFECTION FROM ORAL SEPSIS IN MENTAL DISORDER.

AT a meeting of the Section of Psychiatry of the Royal Society of Medicine on May 14th, with Sir MAURICE CRAIG in the chair, a paper was read by Dr. W. M. FORD-ROBERTSON, of St. Andrew's Hospital, Northampton, on gastro-intestinal focal infection in relation to oral sepsis, with special reference to anaerobes, occurring in cases of mental disorder.

Dr. Ford-Robertson said that this investigation covered 114 cases of mental disorder. Its object was to ascertain the relationship of oral sepsis to gastric function in this class of patient, the disorders presented, and the state of the intestine, especially the colon, consequent upon these conditions. The technique of the fractional test meal employed had been the same in all cases. The chemical analysis consisted, in the first place, in the estimation of free and combined HCl. He described the state of the teeth and tonsils in the patients examined: eleven of the patients were edentulous; and many others nearly so, and in few cases could the state of the gums be said to be healthy. In all but a few of the cases the dental or tonsillar resting juice and intestinal cultures had been systematically studied. Out of the 114 cases 92 cultures of the resting juice were made. In 60 cases where the first culture was positive, the resting juice was allowed to stand at room temperature for twenty-four hours in order to test its germicidal power and then recultured and the growth, if any, compared. Of 47 cases having free HCl in the resting juice, 63.8 per cent. were sterile in the immediate culture and 94.4 per cent. were negative when cultured a second time. Providing free HCl was present in the resting juice, even in moderate degree, bacteria were effectively destroyed, but the story was very different when there was no HCl in the resting juice. The work illustrated the possibility of losing the teeth and maintaining the same infection elsewhere. Gastric function varied from time to time according to the physical and mental state of the individual. Positive variations would in most cases be to his advantage, but loss of secretory function might bring him for days or months into the danger zone of partial anacidity. The analyses of the fractional test meal results in the 114 cases (whose average age was 41 years) were as follows:

Achylia gastrica	5 cases.
Achlorhydria	9 "
Hypochlorhydria	35 "
Normal	53 "
Hyperchlorhydria	12 "

A special group with no free acid in the resting juice numbered 58 cases. Of these 114 patients 46.5 per cent. came within the normal range of acidity, while 80 per cent. of normal individuals came into this same normal group. The author said that from the relationship established between the state of the resting juice and the gastric function in general, it might be expected that severe gastric infection would predispose to the descent of streptococci into the bowel, but, curiously enough, this was not the case. The tracing of the descent of the anaerobes to the colon was very difficult, but in some cases he had been able to follow them from their origin in the tonsils or teeth to the resting juice and into the intestine. Almost 90 per cent. of the cases showed intestinal infection by one or a mixture of three anaerobic species of bacteria—in other words, the infection in the majority of cases was severe. His experience of the examination of the non-mental patient was that severe anaerobic infection was uncommon, but neurasthenic and borderline cases showed a picture approximating to those found in this investigation.

Dr. Ford-Robertson's general conclusions were that in mental disorder gastric dysfunction, especially hypochlorhydria, was present to a much greater extent than in normal individuals; that the importance of free HCl as a bactericidal barrier had been proved; that oral sepsis could be traced through the alimentary canal; that the degree of gastric infection did not increase the expectation of invasion of the intestine; and, finally, that anaerobic methods were essential if the full significance of these special types of infections present in mental disorders was to be realized.

There was no discussion on the paper, but, instead, Dr. Ford-Robertson showed a large number of excellent colour microphotographs of cultures illustrating some of the cases.

DIETARY CAUSES OF PEPTIC ULCERATION.

A MEETING of the Aberdeen Medico-Chirurgical Society was held on May 2nd, with the vice-president, Dr. CHARLES FORBES, in the chair, when Dr. H. E. MAGEE of the Rowett Institute contributed a paper on diet and peptic ulcers in laboratory animals, based on experiments by himself and his colleagues.

Dr. Magee said that the experiments were designed principally to test whether deficient diets had a remote effect on the movements of the isolated intestine. Guinea-pigs were fed on diets which earlier trials had shown to give rise to a high incidence of ulcers in the gastric and duodenal mucosa in these animals, so that the results fell into two categories—physiological and pathological. The diets consisted chiefly of cereals with, in some groups, small

amounts of greenstuff, and in others additions of various inorganic salts. They were, in the former, poor in calcium, sodium, and chlorine; in the latter in potassium; and in both groups the fat-soluble vitamin content was very low. No clear distinction was evident in the results from the respective groups. The animals fed on these diets went rapidly downhill from the start, and in time developed definite signs of malnutrition. When this happened they were killed, their intestines excised, and the movements recorded when suspended in a special nutrient fluid at 38° C. The tracings showed a marked degree of irregularity and disorganization of rhythm. Two types of irregularity were distinguished—hyposensitive and hypersensitive. In the former the range of movement was relatively small as compared with that obtained from the intestines of control animals fed on adequate diets, and the response to adrenaline subnormal. In the latter the movements were relatively very large, and often violent in character, and the response to adrenaline was much exaggerated. The responses to bicarbonates and phosphates also differed from those obtained from normal animals. A large proportion of the animals showed haemorrhages and ulcerative changes in the mucous membrane in the pyloric region, circulatory disturbances round the ileo-caecal valve, stasis of an atonic or spastic type in the same region, and congestion, haemorrhages, or excessive cellular vacuolation in the adrenal cortex. These findings confirmed, in many respects, those of McCarrison and others, and showed that the segmenting movements, of myogenic origin, could be disorganized by improper food. Rowlands having shown that deficient diets caused defective emptying of the bowel, it was the speaker's opinion that the intestinal stasis in his experiments was the result of disorganization of the segmenting, as well as of the more highly developed peristaltic, movements. It was also suggested, in accordance with the findings of Carlson, that the stasis would induce pylorospasm. Agreement was expressed with the view of Cramer that the lesions in the adrenals were due to over-stimulation by the absorption of protein decomposition products, among which were probably histamine, or bodies of a similar type. Mention was also made of the work of Dale and others, who showed that adrenalectomized animals were abnormally sensitive to injections of histamine, and also that the changes produced in the blood by histamine poisoning closely resembled those found in adrenalectomized animals. Further relevancy was added to the citation of these findings by those of Stewart and Rogoff, and of others, who found a high incidence of peptic ulcers in adrenalectomized animals. These results suggested a close relationship between the functions of the adrenals and of the alimentary canal, and further experiments were performed to investigate this point. It was found that the isolated intestines of adrenalectomized rabbits responded to adrenaline in either a hyposensitive or a hypersensitive manner, as in the case of the deficiently fed guinea-pigs. The responses to the potassium and calcium ions also departed from the normal. It was found, moreover, that the response of the intestines of adrenalectomized animals to calcium in bicarbonate containing nutrient fluids was exactly the same as that of the intestines of normal animals in bicarbonate-free fluids, a result which appeared to be correlated with the lowered bicarbonate content of the blood of adrenalectomized animals.

SPIROCHAETAL EMPYEMA.

AT a meeting of the Section of Pathology of the Royal Academy of Medicine in Ireland in the Royal College of Physicians, on April 19th, with the president, Dr. T. T. O'FARRELL, in the chair, Dr. J. MCGRATH showed a patient with spirochaetal empyema.

A farmer, robust in appearance, was admitted to St. Vincent's Hospital on February 8th. He gave a history of "never being sick in his life" until he felt ill on December 23rd, 1928, when his local medical attendant sent him to bed for several days, telling him that he was suffering from influenza. He was out and about again after Christmas, but grew progressively weaker as time went on. On his admission to nospital the temperature was 101° F., the pulse 80, and the respirations 20 per minute. There were no physical signs indicative of chest or other trouble; the urine had a slight trace of albumin, but the sediment contained no pus, blood, or casts. For the succeeding few days his temperature was normal, but at the end of a week it was 99.5° F. in the evening for four days. After February 17th, when he was operated on, the temperature remained continuously normal, the pulse 72, and respirations 20. On February 16th there was slight dullness at the base of the left lung; it was needled and a small amount of brownish red pus was withdrawn. This pus contained many cells and moderately numerous spirochaetes. No other organisms were seen in the smear preparations, and on culture no growth appeared either aerobically or anaerobically. The spirochaetes found were then non-motile and stained easily, being Gram-negative; they were 4μ to 10μ long, rather thick, and with two to eight undulations. They resembled *S. refringens*, but several of them appeared too short and too regularly curved to be this spirochaete. A blood count on February 17th showed red cells 4,120,000 per c.mm. (82 per cent.), haemoglobin 55 per cent., colour index 0.7, white cells 15,680 per c.mm. The red cells showed very slight anisocytosis, and of the white cells 79 per cent. were polymorphonuclear leucocytes, and 1 per cent. were eosinophils. Tubercle bacilli could not be found in the sputum, nor could spirochaetes (which are sometimes to be found in large numbers in bronchiectasis); the Wassermann reaction was negative. On February 17th two ribs were resected, and several pints of tomato-soup-like fluid were evacuated; this fluid gave similar results to the small specimen first examined. A drain was left in. The pleural cavity was still draining, but on April 12th the fluid showed no spirochaetes, and produced a growth of pneumococci and a coliform organism. The patient was given injections of novarsenobenzol, and a vaccine had been prepared from the last cultures of the fluid. The urine, on April 17th, contained a considerable amount of albumin, several hyaline and some granular casts; but the patient's condition appeared to be good.

Dr. MCGRATH said that few cases of spirochaetal empyema appeared to be recorded, especially where not associated with gangrene of the lung and without other organisms. A case with spirochaetes in an empyema but with gangrene of the lung had been recorded by some French observers in May, 1928, but Dr. McGrath had been unable to obtain the original paper. In the present case he was assured that there was no suggestion of gangrene of the lung. The patient's teeth were in good condition, but showed one small and one moderately large cavity. In view of the fact that it had been stated that in cases of tropical bronchopulmonary spirochaetosis the *S. castellanii* could nearly always be isolated from bad teeth, smear preparations of scrapings from the patient's teeth cavities were examined. There were very numerous micro-organisms present, but *spirochaetes could not be found.*

The PRESIDENT said he had never seen a similar condition to that shown by Dr. McGrath. He thought at first that the spirochaete might have come from a cavity in the lung, but understood that clinicians who had seen the case said that this was not so. Professor J. W. BIGGER stated that spirochaetes were found in gangrenous conditions, but nearly always in association with other organisms. It was rare to find them confined to the pleural cavity. Professor BEATTIE drew attention to the large number of spirochaetes present, and their thickness, and thought that they might possibly have come from the teeth, but apparently this was not the cause.

Intestinal Obstruction due to Gall-stone.

Mr. J. L. KEEGAN showed a gall-stone which had caused *intestinal obstruction.*

A woman, aged 70, had had severe pain in the right upper abdomen twelve months previously with vomiting lasting three days; after that she had enjoyed good health until March 7th, when she had severe pain, vomiting, and complete constipation. The vomiting was continuous and she could not pass flatus.

On examination she was collapsed, weak, and with almost imperceptible pulse, anxious facies, an abdomen distended but not rigid, and pain on pressure. On the diagnosis of acute intestinal obstruction the abdomen was opened on the right side with a view to caecostomy to give immediate relief to the obstruction. Finding the caecum collapsed but the ileum distended, a coil of the latter was delivered and a large hard mass was felt in the ileum, which was removed. The transverse colon was intimately adherent to the liver and obscured any sight of a gall-bladder. The patient's condition did not permit any examination to see how the stone had entered the intestines; it weighed 18.15 grams, and formed a complete cast of the gall-bladder.

The PRESIDENT had never seen a case in which gall-stones had caused absolute intestinal obstruction, and asked if there was any history of typhoid fever. Mr. F. J. HENRY said that clinically he had never seen a case of gall-stone obstruction, or a specimen of gall-stones which had caused obstruction. From a perusal of the literature the impression was gained that gall-stone ileus was now much more rare than it had been ten or fifteen years ago, the reason for this being, presumably, that patients now came for treatment earlier than they used to. The gall-stone in this case was an example of the pure cholesterin type, and

the reason why gall-stone ileus was nearly always caused by this type of stone was because the stone could not find any other way out of the gall-bladder except through a fistula. Referring to the site of impaction of the stone, he asked if it had been found at the upper end of the small gut or down below at the ileum. It was stated by most surgeons that obstruction occurred comparatively high up in the small gut, and for that reason vomiting was a very early and very pronounced symptom. Dr. R. A. Q. O'MEARA remarked that hypercholesterinaemia occurred in other conditions besides pregnancy; he thought it possible that there was some other factor in pregnancy which acted in conjunction with hypercholesterinaemia to account for the formation of gall-stones.

MR. KEEGAN, in replying, said that there had been no history of typhoid. The gall-stone was found in the lower third of the ileum, near the ileo-caecal valve.

Colloids in Urine.

Dr. JESSOP, in a communication on colloids in urine, remarked that Weiner had observed that urine contained a factor which inhibited the precipitation of urea nitrate when an equal volume of concentrated nitric acid was added. This factor was investigated in normal and pathological urines, using a technique which had been carefully worked out. The inhibitory factor was found to be present in all the specimens examined. In a certain proportion of urines this inhibition was small; the difference between the solvent power of a 50 per cent. aqueous-acid solution and that of a similar urine-acid solution corresponded to from 0.08 to 0.16 per cent. urea. In other urines the inhibition was sufficient to prevent the formation of any precipitate from concentrations of 2 per cent. urea. A saline solution corresponding in composition to urine gave a small inhibition. Various concentrations of NaCl up to 6 per cent. gave no inhibition. On adding various strengths of colloid solutions to 2 per cent. aqueous solutions of urea an inhibition was observed. In some specimens the inhibition partially disappeared when the coagulable protein was removed.

The PRESIDENT suggested that if the urine were taken by ureteral catheter it would be possible to form a more reliable idea of the amount of colloids it contained than if the urine were passed in the ordinary way.

Dr. WILLIAM FEARON dealt with the nature, amount, and function of the urinary colloids. He pointed out that male urine contained a higher proportion of colloid than female, and raised the question of the relation of urinary colloids to calculus formation. He suggested that the normal colloids of the urine exerted a beneficial action in keeping the less soluble solid constituents of urine in solution. Dr. J. MCGRATH thought that colloids in urine might be specific, in that they kept the urea in solution; he had found that other colloids did not act as well as urinary ones for this purpose. As regards the origin of the colloid, if it came from the capillaries it was doubtful how it passed through them. Dr. R. A. Q. O'MEARA agreed with Dr. Fearon that the normal colloids in urine possibly acted as a protective mechanism against calculus formation. Normal urine contained no irreversible colloids, since these only gained entry when the kidney or urinary tract was inflamed. In addition, a crystalline nucleus for calculi was very common, and urinary calculi not infrequently originated without previous inflammation. He discussed the relation of vitamin A deficiency to calculus formation, and suggested that defective formation of normal urinary colloid following such deficiency might explain the occurrence of calculi in experimental animals fed on a vitamin-deficient diet. Professor BEATTIE mentioned that some of the urine examined had been from cases of diphtheria and some from cases of whooping-cough; in all of these cases a toxin was being absorbed, and the urine might contain toxin.

Dr. FEARON, replying, said he believed that colloids came from several sources, and that some were actually excreted by the kidney. Probably a great deal came from the bladder, and he agreed with the president that it was advisable sometimes to compare the colloids in urine taken by catheter with that passed in the ordinary way. He looked forward to the time when it would be possible to take kaolin precipitates and trace the adsorbed colloid.

Reviews.

BLOOD-VESSEL TUMOURS OF THE BRAIN.

A somewhat large monograph[1] of about 200 pages on the rare lesions of blood-vessel tumours of the brain, by CUSHING and BAILEY, has just reached us. The book is in the main a retrospective investigation of those lesions which have been treated in Dr. Harvey Cushing's clinic, with a thorough review of the subject in the light of more recent knowledge. In addition, a wide survey has been made of the literature, which in many cases is scanty and incomplete, and the whole subject has been placed on a practical basis; this should clear up many obscurities, and serve as a basis for future investigation.

To bring out a book of this kind requires a vast amount of work, and its production is very costly. The authors are to be congratulated on the high standard of the former, and have been singularly fortunate with regard to the latter, in that the expenses have been defrayed through the offices of a grateful patient. The subject is dealt with in detail entirely from the clinical, surgical, post-operative, pathological, and histological points of view. The aim of the authors has been certainly achieved, although they naively suggest that it may appear Victorian in character to a younger generation of physicians and surgeons, whose tendency is to forsake the post-mortem and dissecting rooms to worship at the shrines of experimental physiology and biochemistry.

The substance of the work has been divided into two parts: (1) the angiomatous malformations, (2) the angioblastomas or true neoplasms of blood-vessel elements. The angiomatous malformations are considered to be of congenital origin, and are clearly distinguished from the blood-vessel tumours by the fact that compressed nervous tissue is invariably present between the loops comprising them. The malformations are further subdivided up into (1) telangiectases, (2) angioma venosum, (3) angioma arteriale. They occur predominantly in the cerebral hemispheres, and often provoke epileptiform attacks. The venous angiomas are sometimes associated with cutaneous trigeminal naevi, whereas the arterial angiomas are often recognized by an audible bruit, sometimes a choked disc, and unilateral exophthalmos. Surgical treatment is unsatisfactory. The angioblastomas are composed of angioblastic elements. Their site of election is in the cerebellum, and they are largely cystic, and when properly stained show a network of reticulum, which serves to distinguish them. One interesting group of these tumours, which is often associated with an angiomatous condition of the retina, angiomas of the cord, and cystic lesions in other organs and may show a familial tendency, was described and differentiated by Lindau, and the recent appearance of his monograph has evidently suggested to Cushing and Bailey a review of their material. The tumours should be treated by extirpation, and when cystic tumours are encountered care should be taken to remove the mural nodule, otherwise recurrence of the cyst is to be expected.

It would appear that one of the main purposes of this study was to explore Lindau's work, and the conclusion of the authors is that Lindau came to regard these lesions associated with angiomatosis of the retina as of more common occurrence than they actually are. It must be noted that in this series only one out of eleven cases was a true case of Lindau's disease, although in six of the living patients their fundi were only examined for this condition at a later date. In the extensive bibliography we are struck by the paucity of references to work emanating from this country. Sargent and Greenfield have done something to remedy this defect by collecting some of their specimens for a paper in the course of publication; but, speaking generally, there is a tendency among British workers to isolate their work in watertight compartments, which hinders any semblance of organized co-operation or mass production. As a product of concerted effort and unified

[1] *Tumors Arising from the Blood-vessels of the Brain.* By Harvey Cushing and Percival Bailey. London: Baillière, Tindall and Cox. 1928. (6½ × 9½, pp. x + 219; 159 figures. 21s. net.)

control Cushing and Bailey's book is an excellent example, and it should stimulate our special hospitals to devise better schemes for a more fruitful exhibition of their labours.

HYGIENE AND PUBLIC HEALTH.

WE reviewed the sixth edition of PARKES and KENWOOD'S *Hygiene and Public Health*[2] on March 2nd, 1918 (p. 261). The eighth edition of this textbook, so well known to students for the diploma of public health, makes its reappearance with Dr. HAROLD KERR as co-author in place of Dr. Louis C. Parkes; Dr. H. M. Hanschell has been called in to assist in regard to that part of the book dealing with the tropics. The task of revision, and especially of addition, has been well performed. There is perhaps more of a tendency to introduce sanitary law—many of the older generation of readers regret the omission, several editions ago, of an excellent summary of public health legislation as it was then. There is also perhaps a tendency to quote more from special reports, a feature all to the good when the reading, labour, and care that have been devoted to their writing are borne in mind.

The authors are generous in mentioning the works of their fellow writers. We note that they agree with Dr. W. G. Savage in holding that Professor v. Ostertag's scheme for segregating and slaughtering only open cases of tuberculosis among bovines, while reducing milk infection, cannot eliminate tuberculosis among these animals. Unfortunately, however, in spite of the publication of sound English and German work on this point, they insist on teaching that pasteurization of milk kills tubercle bacilli. Another dictum of the authors is to the effect that there is probably no relationship between spirochaetal jaundice and the ordinary epidemic form which occurs in this country. As regards methods of treatment of sewage, they state that probably every one of the methods referred to may be made to give satisfactory results; questions of economy of plant and time, of working and maintenance, and of the relative applicability of the process to local wants and facilities must and will ultimately determine the choice.

In a number of places throughout the book we seem to detect an absence of the critical faculty: we are certainly not always told the opposite side, which is surely advisable in post-graduate teaching and in the presentation of a subject to administrative colleagues. The plan of one part of the book appears to be to present to the reader an account of a very considerable number of appliances and methods, some of which, at any rate, would not be considered when arranging for new installations; condensation or omission would provide space useful for the instilling of principles. We are given very few footnotes which might contain references to papers useful to fellow administrators. The information given on tropical diseases, if occasionally a trifle dogmatic, is very sound. The relatively small cost of the book is doubtless responsible for its comparatively uninteresting and undistinguished format. A number of useful new illustrations have been included; the index has withstood satisfactorily a substantial test by the reviewer.

A perfect textbook on public health would take years to write and would probably have to be issued at a prohibitive price. Here we have a quarry of concise information valuable to students and practical workers, a bargain at the price asked for it.

APPLIED ENTOMOLOGY.

PROFESSOR WARDLE is already well known as the joint author, with the late P. S. Buckle, of the *Principles of Insect Control* (1923). He has now produced a second book, not unlike the first, entitled *The Problems of Applied Entomology*,[3] in which he brings his account of the subject up to date. In the first 250 pages or so he discusses a great range of general topics: for instance, the behaviour of insects, their resistance to climate, and their relations to food plants and hosts; also more practical problems, such as the composition and action of insecticides and fumigants, and methods of cultivating plants so as to make them resistant to the attacks of insects. In this part of the book the author shows that he has read very widely and that he can write a fair and balanced summary. It is delightful also to see that he is not afraid of going to the very root of the matter, for he considers what is fundamental to the spreading power of insecticides and their toxicity, and the mathematical aspect of the increase of a population of parasites at the expense of a population of hosts. Then, again, in discussing the relation between the length of life of an insect and the temperature, the author pursues the matter right out of the range of entomology, and discusses the facts in relation to the laws of Van't Hof and other physicists. In his discussion on the relation between insects and the climate in which they live the author is dealing with a subject of particular complexity and of very great practical importance, and he manages to combine the results of field observations and controlled experiments in laboratories, and to present the whole in a balanced and compact way.

The second part of the book deals with the principal entomological problems of the world. Professor Wardle divides the surface of the earth into ten main areas, which are discussed in turn. In the nature of things this part of the book is rather a collection of abstracts, but it is certainly useful for reference, and we have been unable to discover grave omissions in it. In these pages a medical man can find a short account of the carrier of plague in India, or the Anopheles of the Mediterranean, etc. It will be understood that the applications of entomology to medicine are not discussed by themselves, and that no one part of the book is of particular interest to the medical reader, but it is clear that the author's reading has included medical entomology in its scope.

It might be wished that Professor Wardle had shown a little more of his personal feeling in selecting his material. The book is an able summary of the literature, but it is rather cold and impersonal; though it is useful, it does not rouse our enthusiasm in any particular part. The medical entomologist will find a few errors in fact: for instance, it is misleading to say that the relapsing fever of Africa, which is carried by *Ornithodorus moubata*, is due to *Spirochaeta berbera*. It is curious that the account of malaria in India contains no reference to Christophers, whose work is probably of much greater importance than that of any other individual. The book abounds in wrongly spelt scientific words. With the ordinary words the printer's proof reader has dealt quite carefully, but we think he must have left all the italicized words to the author.

SPECIFIC TREATMENT OF PNEUMONIA.

DR. F. T. LORD'S Harvard Health Talk on *Pneumonia*,[4] which was reviewed in our issue of September 15th, 1923, now summarizes in a second edition the advances, especially those in specific treatment, since 1922. Felton in 1921 found, by the simple method of diluting multivalent antipneumococcal serum with water, that from the resulting precipitate a concentrated antibody solution, containing small quantities only of horse serum, could be made, and that this is effective not only against Type I but probably also against Type II pneumococcus infection. This antibody solution, being concentrated, is given intravenously in doses of 5 to 10 c.cm., as contrasted with 100 c.cm. of the unrefined serum against Type I pneumococcus, and, being multivalent, can be given early before the type of the infecting pneumococcus has been determined. The three forms of reaction that may follow injection of serum are clearly described; they are: an immediate shock-like reaction; a thermal reaction, not uncommon after Felton's antibody solution, coming on usually within an

[4] *Pneumonia.* By Frederick Taylor Lord, A.B., M.D. Second edition. Harvard Health Talks No. 9. Cambridge, Massachusetts: Harvard University Press; London: Milford, Oxford University Press. 1929. (Fcap. 8vo, pp. 84. 4s. 6d. net.)

hour of the injection and characterized by transient rise of temperature and the pulse and respiration rates; and the serum disease appearing a week or more later.

In our present issue (p. 943) Dr. J. G. M. Bullowa, professor of clinical medicine in the New York University, gives an account of his experiences with serum treatment of the pneumococcus pneumonias at the Harlem Hospital. It will be seen that he is convinced not only that there were fewer deaths in the serum-treated cases, but that the administration of serum shortens the time of illness in severe cases. Another article on the same subject by Professor Bullowa appears in the April issue of the *Bulletin of the New York Academy of Medicine*. He recognizes that serum treatment, with its frequent injections, its careful typing, its blood cultures, and its antibody tests, requires expert and special skill. He hopes, however, that the technique may be simplified, and that better and cheaper serum will become available as the demand increases and more horses are immunized. "It is only by early diagnosis and prompt use of the serum in the hands of general practitioners that the dramatic results we have witnessed can be extended, and mortality from pneumonia gradually reduced."

CLINICAL NEUROLOGY.

DR. NEUSTAEDTER in the preface to his *Textbook of Clinical Neurology*[1] states that he has endeavoured to arrange his material in a manner different from that usually employed in textbooks of neurology. In place of the customary pathological classification he has sought to present an account of diseases under the headings of symptoms. This is an attempt which was bound to fail, for the reason that there are few diseases of the nervous system which have only one symptom, and symptomatological classification thus becomes purely arbitary. Dr. Neustaedter has, indeed, made the worst of both worlds. When he is consistent he is saddled with an arrangement which leads to the inclusion of tabes dorsalis, tumour of the cerebellopontine angle, and disseminated sclerosis in one chapter as "ataxias." But for the most part he is inconsistent, and reverts to the time-honoured plan of neurological textbooks, with the familiar "tail" of endocrine disorders, some of which cannot by any stretch of imagination be described as neurological, and lastly hysteria and neurasthenia. Unfortunately the material arranged is no more satisfactory than the arrangement, being in many respects inadequate and in places inaccurate. Thus we are told that a lesion limited to the pyramidal tract produces only a hemiparesis, and that in complete hemiplegia tecto-spinal, vestibulo-spinal, and rubro-spinal tracts are also involved. It is also stated that "pituitary neoplasms are always accompanied by bitemporal hemianopia." The views expressed on "optic neuritis" and "papilloedema" are hard to follow, and it is difficult to make sense of the statement that "optic neuritis is a constant accompaniment of choked disc, and often precedes papilloedema." Treatment by induced malaria is described under "cerebral syphilis" and merely alluded to under "general paralysis." In the account of Schilder's encephalitis there is no mention of the cardinal symptom, loss of vision; and no reference is made in the book to congenital intracranial aneurysm.

NOTES ON BOOKS.

MACCALLUM'S *Text-Book of Pathology*[2] is now in its fourth edition. This work, which has been well received in this country, differs from most textbooks on the subject in the point of view adopted by the author in his exposition. No division is made into general and special pathology, but the whole work is constructed upon the idea that all pathological disturbances are the result of some form of injury or of the immediate or remote reactions of the body to injury. Thus the primary classification is that of various types of injury—traumatic, bacterial, and so forth. This point of view has its advantages; it assists in keeping the relation of causes to pathological processes in the foreground, and thus obviates the tendency towards a mere descriptive anatomy of lesions. Another feature which has furthered the popularity of the book is the great beauty of the illustrations, which are not surpassed, possibly not equalled, by those in any other textbook on the subject. The present edition shows evidences of extensive revision in almost every section. It has been deemed desirable to shorten or omit chapters on so [illegible] immunity, the acid-base equilibrium, and [illegible] and this has permitted of the introduction of new matter without increasing the size of the volume to any considerable extent. The additions, which include discussions on recent advances in our knowledge of bilirubin production, calcium metabolism, yellow fever, goitre and cretinism, vitamins, rickets, allergic reactions, and the reticulo-endothelial system, serve to bring the volume well up to date.

The second number of the new series of the *Annals of Medical History*,[3] which now comes out every other month, opens with Dr. S. C. Harvey's account of haemostasis, the history of which he traces through the ages with a number of illustrations of instruments used in the arrest of haemorrhage, some from Fabricius Hildanus, whose portrait adorns the cover. The frontispiece represents John Coakley Lettsom, of whom Sir StClair Thomson wrote in the January number. A letter to Lettsom forms the opening paragraph of Dr. George C. Peachey's interesting article in this number, entitled "John Fewster, an unpublished chapter in the history of vaccination." Dr. W. S. Miller of Wisconsin writes with information of an interesting personal nature about William Beaumont, Alexis Bigigan, better known as St. Martin, who survived for sixty years the accident which caused the famous gastric fistula, and Elisha North (1771-1843), who gave the first description in America of cerebro-spinal fever, and had two deaths only among more than 200 cases. In the account of Dr. James and his medical dictionary, Dr. C. W. Burr of Philadelphia mentions that the author of the dictionary was the grandfather of G. P. R. James the novelist. In an attractively written sketch of Gabriel Honoré de Riquetti, Count of Mirabeau, Dr. R. A. Moore concludes that his death, at the age of 42, was due not to poisoning, but to cardiac infarction supervening on arteriosclerosis and chronic nephritis. In his biography of Arnold Adolf Berthold (1802-1861) Dr. Homer P. Rush shows that in 1849 he anticipated Brown-Séquard's conception of an internal testicular secretion in 1889. Dr. T. N. Toomey draws attention to Venegas's *Compendio de la Medicina*, published in Mexico in 1788, as the earliest general medical treatise to appear in the Western hemisphere. The travels of Garcia da Orta in India and the East enabled him, as Lieut.-Commander L. H. Roddis, M.C., U.S.N., shows, to write, in 1563, in Portuguese, "Colloquies on the drugs and spices of India," and thus to be the first European writer on tropical medicine and a pioneer in pharmacognosy. A memorial group of the Harvey family is described by Sir D'Arcy Power, who reproduces the portraits occupying one wall of the drawing room at Rolls Park, Chigwell, Essex, belonging to the Lloyds, descendants of Eliab, the brother of William Harvey. Among the book reviews are those of the fourth edition of Garrison's great *History of Medicine*, and two works by Dr. Charles Singer.

The alkaline reserve,[4] by AMBARD and SCHMID, contains an account of the opinions of the Strasbourg Medical School on all the questions concerning respiratory, circulatory, and renal function and pathology that are associated so closely with the central problem of the factors governing the alkaline reserve. The subject is one of the most complex in modern chemical pathology, and the volume makes difficult reading. Professor Ambard's views, however, although original, are always definite and clear. The volume is one that will repay study by all who are interested in this problem.

PREPARATIONS AND APPLIANCES.

A POCKET ELECTRIC OTOSCOPE.

AN "auriscope" adapted for use with the fountain pen type of electric torch has been manufactured by Messrs. *John Smith and Son, Ltd.*, 26, Gibson Street, Hillhead, Glasgow. It can also be used as a throat lamp, and facilitates various diagnostic and operative procedures. A lens at the back of the apparatus can be removed, admitting the passage of instruments through the speculum; various sizes of specula are supplied. The apparatus is adapted to clip in the waistcoat pocket, and is transportable without inconvenience. Its price is 32s. 6d. complete; in connexion with it a Lucae's myringotome for paracentesis operation can be supplied, and also a tongue depressor can be fitted to the torch.

British Medical Journal.

SATURDAY, MAY 25TH, 1929.

THE CONDITIONED REFLEXES.

IT is now almost sixteen years since there appeared in the *British Medical Journal*[1] an account—one of the first in English—of the investigations on what were there called the conditional reflexes, but for which the name of "conditioned reflexes" is now most commonly used. That address was, however, by no means an early one in the history of the development of the subject, which, since 1901, has been steadily growing in the hands of Professor Pavlov and his numerous colleagues and pupils. A further large mass of data has since been accumulated, the main outlines have been incorporated into some modern textbooks of physiology,[2] and a comprehensive treatise on conditioned reflexes has now appeared as a book of some size,[3] which was reviewed in these pages on October 1st, 1927 (p. 596), so that the essentials of the subject, both as regards methods and results, are now reasonably accessible to English-speaking readers. The subject is, however, so interesting and important, and so much of its literature is in Russian, that any fresh addition to the literature in the English language is invariably welcome. It is therefore with especial pleasure that we welcome an English edition of a collection of Professor Pavlov's various lectures and addresses.[4] The book has a personal note which should make it especially valuable to many who, though in a sense his followers, have not had the advantages of actual contact with Professor Pavlov. For instance, a most attractive feature is the opening biographical sketch by Dr. Horsley Gantt, which gives us a very good introduction to Professor Pavlov and some incidents in his remarkable career.

Almost without exception Pavlov's experiments have been carried out on the dog—"this faithful and friendly representative of the animal world." The opinions of so great a physiologist on the subject of animal experimentation are therefore especially interesting: "As is known, vivisection has excited in many countries of Europe an energetic objection from the uninitiated. These protests have at times seriously interfered with the progress of biological investigation (for example, in England). But what is the basis for this? The feeling of pity. . . . But the experimenter also has this feeling. . . . The human mind has no other means of becoming acquainted with the laws of the organic world except by experiments and observations on living animals. . . . If we consent to the torture and killing of thousands of even our fellow men in wars, then how can we object to the sacrifice of a few animals on the altar of the supreme aspiration of man for knowledge in the service of a high ideal, the ideal of attaining to truth?" Passion for truth is indeed Pavlov's outstanding characteristic, and "in his own words," to quote Dr. Gantt, "uttered with a reverberation of his whole being and with such awe-inspiring force that it compelled silence during protests made to unwelcome statements in one of his lectures, 'I am speaking only the scientific truth, and whether you will or no you must hear it.'"

The history of the development of the subject as given by Pavlov is most valuable and interesting. "I entered this field under the influence of a powerful laboratory impression," he writes. "For many years previously I had been working on the digestive glands. . . . I began to investigate the question of psychic secretion with my collaborators Drs. Wolfson and Snarsky. . . . Snarsky . . . undertook to analyse the internal mechanism of the stimulation from the subjective point of view—that is, he assumed that the internal world of the dog—the thoughts, feelings, and desires—is analogous to ours. We were now brought face to face with a situation which had no precedent in our laboratory. In our explanation of this internal world we diverged along two opposite paths. . . . Snarsky clung to his subjective explanation of the phenomena, but I, putting aside fantasy and seeing the scientific bareness of such a solution, began to seek for another exit from this difficult position. . . . I decided finally . . . to remain in the role of a pure physiologist—that is, of an objective external observer and experimenter, having to do exclusively with external phenomena and their relations." From this point onwards the general trend of the investigations steadily confirmed the correctness of this attitude, though when obstacles were met with there was at first a tendency, which got less and less, to apply psychological explanations.

The view that the cerebral activities were essentially reflex in nature originated with "the father of Russian physiology," I. M. Setchenov, in 1863, and it was to the reading of Setchenov's book during his youth that Pavlov attributes the direction of his thoughts along these lines. The conviction has steadily increased that "along this path will be found the final triumph of the human mind over its uttermost and supreme problem—the knowledge of the mechanism and laws of human nature" which "will deliver man from his present gloom, and purge him from his contemporary shame in the sphere of interhuman relations." "Why," he asks, "had we formerly, like cowards, returned to the old subjective methods? The secret is simple: because the subjective method is the method of thinking without considering real causes, because psychological reasoning is indeterminate reasoning, recognizing phenomena, but knowing not whence they come nor whither they lead."

The story unfolds as we read these lectures in the order in which they were given. First the bare account of the fundamental phenomena, and some lectures dealing with removal of parts of the cerebral cortex. Steadily the importance of inhibitory phenomena is recognized, and thus the need arises for specially constructed laboratories in which to carry out the experiments. In 1909 Pavlov announces "with a feeling of pride . . . that my native country has answered promptly my call for a new type of laboratory." The construction and equipment of this was delayed by war and revolution, and although the Soviet Government appears to have done all in its power to assist Pavlov, the institution was not properly completed and equipped until 1925. In other lectures the processes of inhibition and differentiation, particularly with regard to sleep, are developed. The experiments on sleep arose out of the observation that some of the animals habitually fell into a deep sleep at certain stages of the experiments, and on

[4] *Lectures on Conditioned Reflexes*. Twenty-five Years of Objective Study of the Higher Nervous Activity (Behaviour) of Animals. By I. P. Pavlov, M.D. Translated from the Russian by W. Horsley Gantt, M.D., B.Sc., with the collaboration of G. Volborth, M.D., and an introduction by Walter B. Cannon, M.D., Sc.D. London: M. Lawrence, Ltd. 1928.

following up the subject it became clear that there is a very close relation between the states of inhibition, hypnosis, sleep, and certain pathological states.

Altogether this group of papers represents an interesting and valuable addition to our literature of the subject, and Dr. Horsley Gantt is to be congratulated on the work which he has done in making it available. Our readers will recall that Dr. Gantt contributed to this *Journal* a series of articles entitled "A Medical Review of Soviet Russia," which appeared periodically from June, 1924, to October, 1927. In more than one of these Pavlov's work on conditioned reflexes was dealt with; the article published in the issue of June 11th, 1927 (p. 1070), being almost entirely devoted to that subject. Mention might also be made of his lecture given to the International Physiological Congress held in Edinburgh in 1923, a report of which was published in the *Journal* of August 11th of that year.

THE ACTION OF THALLIUM.

IT was long after the depilatory action of thallium was discovered that its use for denuding the scalp was popularized on the Continent by Buschke. Quite a voluminous German literature, however, had accumulated before any considerable use of thallium was made in the English-speaking world, and it is only in the last year or two that the therapeutic value of salts of that metal has been discussed in the medical journals of Great Britain and America. Published accounts of the mode of action of thallium are scarce, and the toxicologists, if the latest edition of Taylor's *Medical Jurisprudence* is a guide, have not much to say on the subject. Thallium was brought prominently to notice lately when, by accidental overdose, it was the cause of three deaths. In those cases the dose given seems to have been 5.6 times that intended, and the fact that it was such gross overdosage which caused disaster may perhaps have masked, for those not already familiar with the drug, its great toxicity even when given in dosage accurately prescribed and measured in proportion to naked body weight and with regard to the patient's age.

The obvious advantages of thallium are great: its use requires no costly and elaborate apparatus, and it has never caused permanent baldness. The difficulties attaching to its administration are, however, considerable. It appears that the minimum effective dose is one which may, and quite frequently does, produce undesirable even if not serious symptoms. In recorded series of cases the occurrence of bone and joint pains, often severe and requiring treatment in bed, is frequently mentioned. Polyneuritis, myalgia, hyperaesthesia, and other symptoms have been observed. Fuld[1] describes severe poisoning in a boy aged 12 with no signs of puberty, where dosage was accurately given at 8 mg. per kilo of body weight. Pain in the knee, and later polyneuritis, developed, involving the sciatic, tibial, and peroneal nerves. The pains were extremely severe, very resistant to treatment, and lasted for three weeks; for months afterwards the boy was in a debilitated condition. Fuld quotes Divella-Bary and Pasini as recommending the abandonment of thallium, and, while not going quite so far himself, he thinks that, at least until an effective antidote is discovered, the use of the metal should be strictly confined to children under 10 years of age. He also gives an analysis of the symptoms noted in a long series of published cases of mild poisoning. There seems to be no way out of the difficulty by repeating very small doses until either the desired effect is produced or warnings to discontinue appear, for the poison is cumulative, and a poisonous dose may have been given before the first sign of trouble arises. The greater need for caution and further study would seem to be indicated by Dixon's[2] demonstration that the action of thallium is not locally upon the hair follicles, but upon the cells in the course of the fibres of the autonomic system, which are affected by thallium much in the same way as are the spinal ganglia by strychnine, allowing stimuli to pass much more readily and forcibly than normally. There is reason to believe that some influence is exercised upon the endocrine glands by the close association of the suprarenals with the sympathetic. The danger of thallium after puberty admits of no doubt.

Serious acute poisoning has been studied in the case of a woman who attempted suicide by thallium rat poison (celiopaste).[3] After some days she had severe pains in the legs and back, neuritis with partial paralysis, the reaction of degeneration, and disturbances of the function of bladder and rectum. Eosinophilia and lymphocytosis occurred; there were wasting, albuminuria, and reduction of the gastric hydrochloric acid. The last has also been reported in chronic cases. In experimental acute poisoning changes in the spinal ganglia and peripheral nerves have been reported.[4] Chronic poisoning by thallium in industrial work has provided opportunity for study of its effects. Buschke[5] and Teleky[6] report lymphocytosis and eosinophilia as characteristic, and both have observed optic atrophy. The former noticed interference with bone development, and the latter records the case of a workman whose loss of hair only occurred after two and a half months of exposure. A more detailed study of chronic poisoning, experimentally produced in animals, has been made by Buschke and others.[4] They found optic atrophy and some degenerative changes in the kidney tubules and liver, but no definite changes in the endocrine glands.

The acetate of thallium is the salt employed in therapeutics, but various others have been tried in animal experiments. The chloride is insoluble, but all the others injected subcutaneously have the same effect. Dixon noted that the depilatory effect was not exercised if thallium acetate was applied to the skin, but Lutz,[7] using ointment of thallium acetate in 5 per cent. strength, found that in rabbits and guinea-pigs a fatal result followed in four days. He states that cumulative action occurs with small doses by this method, and advises gloves in the handling of thallium salts.

THE CLEVELAND DISASTER.

A CATASTROPHE unparalleled in recent years occurred at Cleveland, Ohio, on May 15th, when, as a result of a series of explosions, the Clinic Hospital founded by Dr. George Crile was destroyed by fire, and 127 persons, including patients, nurses, and doctors, lost their lives. The first explosion occurred in the basement used for the storing of *x*-ray films; the second in the chemical laboratories, where it blew out all the windows on one side of the building and released the poisonous fumes which had been generated as a result of the first explosion. Immediately afterwards

fire broke out, and in a few minutes the whole building was enveloped in flames. Many persons were killed directly by the explosions; others, including passers-by in the streets, by the poisonous fumes. So rapidly did the fire spread that, notwithstanding the efforts of the firemen and of numerous rescue parties, it was impossible to save many of the patients, and they perished in their beds. Even some who were not bedridden or overcome by poison gas found their escape cut off by fire, and their dead bodies were discovered in one part of the hospital by the rescue parties. At the time of the first explosion there were over 350 persons in the hospital, and the immediate death roll was no fewer than 95. Later on it was reported that this number was steadily increasing, and that the medical staff had little hope of saving some of the survivors who were suffering from the effects of poison gas. The cause of the disaster is at present unknown, and will naturally be the subject of an official inquiry. The theory generally supported is that the spark causing the first explosion was generated from the crossing of two wires in an *x*-ray apparatus, and that the fireproof safety door of the room containing *x*-ray films had, contrary to rules, been left open. The combustion of *x*-ray films released dense clouds of hydrocyanic acid and bromine, which were diffused rapidly through the building and into the neighbouring streets. Near the *x*-ray films there were cylinders of oxygen, whose contents, released by the explosions, added to the intensity of the flames, which within two hours reduced the hospital building to a mass of ruins. Rescue work was carried out with gallantry and efficiency, and many of the patients were conveyed to safety by firemen and volunteer workers who were protected by gas masks. Fleets of motor cars were commandeered as emergency ambulances, and all the medical and nursing staff of the clinic, with doctors residing in its neighbourhood, devoted themselves to rendering first aid to the rescued. Among the measures adopted to save the lives of those who were overcome by poison gas were the administration of oxygen and blood transfusion, though, unfortunately, with very little success. Several members of the staff, doctors and nurses, died while engaged in rescue work; in all, six of the staff physicians, including Dr. John Phillips, one of the founders of the clinic, lost their lives. At an inquest held on May 16th the coroner announced that blood tests had proved a large number of deaths to have been caused by the inhalation of hydrocyanic acid and bromine. On May 17th it was reported from New York that the number of dead had reached 127, and about twenty of the victims were still in danger. The deepest sympathy of the British medical profession will go out to Dr. Crile and his colleagues, and to all those who have suffered as a result of this appalling calamity.

ROYAL SOCIETY CONVERSAZIONE.

THE spring conversazione of the Royal Society was held on the evening of May 15th, in the society's rooms at Burlington House, when the guests were received by the president, Sir Ernest Rutherford, O.M. One of the most interesting exhibits was that of Mr. Bryan Matthews, who demonstrated the moving iron oscillograph and its use in recording sensory nerve action currents. When a nervous message passes along a nerve trunk changes of potential occur at its surface; these changes are in strength about 20 microvolts, and last about two thousandths of a second. The apparatus for recording them includes non-polarizable electrodes, which lead off the potentials from the nerve to the grid of a valve amplifier by four resistance capacity coupled valves. The amplified potentials are then applied to the grids of four five-electrode valves, which drive the oscillograph. The moving system has a natural frequency of vibration of 6,000 per second, and in this way an exact physical record is obtained of the impulses which constitute a sensation on their way to the brain. Further details of this apparatus, which will possibly prove to be of great diagnostic value, are to be found in the *Journal of Physiology*, June 25th, 1928. In a later article (ibid., March 20th, 1929) Mr. Matthews describes a method of recording under identical conditions the electrical responses accompanying single impulses from skin and muscle receptors, and of distinguishing between them. A paper on the physics of the instrument will be published shortly. From the Strangeways Research Laboratory, Cambridge, were sent illustrations of the latest work in connexion with tissue culture. Dr. R. G. Canti and Mr. F. G. Spear demonstrated the effect of radium and low temperature on mitosis *in vitro*. Tissue cultures were exposed for a short time to radium and subsequently incubated. It was found that irradiation caused first a reduction in mitosis, which was most marked eighty minutes after the removal of the radium. This was followed by a compensatory increase, which reached a maximum in just under three hours; after six hours mitosis had fallen to the normal. A strikingly similar effect was produced by the temporary exposure of cultures to a low temperature. Mr. Spear also demonstrated the delayed lethal dose of radium on tissue cultures, and showed that the prolonged irradiation of tissue inhibited cell division and also the wandering out of cells from the explant. Two excellent cinematograph demonstrations were given during the evening by Dr. Canti, illustrating dramatically cell structure and division, wandering cells and fibroblasts, and phagocytosis in malignant growths. Dr. R. J. Ludford provided a collection of microscopical preparations and enlarged photographs, demonstrating the relation of nerve fibres to normal and malignant epithelium. The occurrence of free nerve endings among the normal epidermal cells was clearly visible, and the connexion of these with a subepithelial nerve plexus was traced. No such nerve endings were present among the cells of cancerous growths produced by the application of tar to the skin of the mouse, although they were to be seen in the thickened epidermis characteristic of the early stages of tar painting. Contrary to views previously held, there appeared to be no innervation of the actual tumours. Sir Almroth Wright gave a demonstration of the phenomena of "intertraction" between serum and saline solutions, water and saline and sugar solutions, and alcohol and water. He demonstrated the connexion between molecular diffusion and intertraction, and the conversion of the one into the other by altering the surface tension. The Cambridge Instrument Company exhibited a portable electro-cardiograph, which enabled four films to be exposed without resorting to the dark room; the records produced were comparable with those obtained from the standard Einthoven galvanometer. Dr. Tattersfield of the Rothamsted Experimental Station showed tropical leguminous plants which are poisonous to fish and insects, and preparations of the active principles of English-grown pyrethrum; also an apparatus for determining quantitatively the toxicity of contact insecticides. The exhibits of more general interest included a portrait in wax of Sir Isaac Newton, lent by Sir Richard Glazebrook, and some photographs by Professor W. A. Bone and Mr. R. P. Fraser of flames travelling horizontally through gaseous explosive mixtures. One interesting point brought out was the importance of moisture, which functioned as a catalyst, and the similar action of a magnetic field. Mr. Campbell Swinton showed photographs of eminent men of science, including a wet-plate photograph, which he had taken as a boy in 1877, of Professor Huxley. The Marine Biological Association illustrated their herring investigations at Plymouth by specimens and diagrams, indicating how an increasing knowledge of the habitat and growth of young herrings, and the spawning and migrating habits of the more adult fish, was leading towards the ultimate explanation of the violent fluctuations to which

commercial fisheries are subject. Mr. George H. Gabb showed the silver pocket sundial of the first Duke of Marlborough, whose arms and motto are engraved upon it, together with the latitudes of such towns in his campaigns as Antwerp, The Hague, and Frankfort. Pocket sundials were often carried to regulate the time of their owners' watches, and the present exhibit was no doubt used by the Duke for this purpose.

THE TREATMENT OF CATARACT.

CATARACT is not so common in this country as certain other diseases that threaten the sufferer with blindness, but it has the inestimable advantage in that for the majority of patients there is a good prospect of recovery of sight by appropriate operative measures. It is natural that with operations of such delicacy and of such critical importance to the patient there should be much consideration of ways and means, and that different operators should find they obtain their best results by different methods. All aim at the removal of the obstructing cataract from behind the pupil, all aim at removing it with the minimum of disturbance to the eye, and all aim at securing the greatest freedom from risk of subsequent decline of vision. There is also a common measure of agreement that a form of operation that does the least damage to the eye and removes the cataract most completely is the one that will secure the best vision and the greatest freedom from untoward sequelae, both immediately after the operation and in subsequent years. A second and enlarged edition[1] of Colonel Henry Smith's book *The Treatment of Cataract* stimulates interest in a review of the situation. India is the country where cataract is more common, perhaps, above all other countries. The experience that is there obtained of operative measures, so far as quantity goes, cannot be rivalled. In quality also there is unrivalled manipulative skill, though it must be acknowledged that mere quantity in opportunity does not necessarily secure this. The skill of European operators is well recognized, although, happily for our Western peoples, cataract is not common, and is probably getting less common as standards of living improve. The earliest known form of operation is that styled "couching." By means of an instrument introduced into the eye the cataract was pushed bodily from its position behind the pupil down to the floor of the posterior chamber of the eye. The effect was immediate: a clear open pupil with restoration of vision. But, alas! the effect was not permanent, for, even when the operation was performed with perfect surgical cleanliness, the dislocated lens within the eye acted as a foreign body, which set up chronic inflammatory changes and ultimately irremediable blindness. Such were the results of perfect technique; the effects that follow the dirty methods of peripatetic bazaar practitioners in India may well be imagined. Couching, therefore, is barred; the cataract must be removed from within the eye. Grave and prolonged consideration has been given in India, in Europe, and in America to the respective advantages and disadvantages that attend removal of the cataract with its capsule entire, and removal leaving the capsule within the eye. On the face of the proposition the capsule should go with the cataract, but the ease with which the cataract will leave its capsule is greater than the ease with which the whole structure can be detached by rupture of the lens ligaments. Colonel Henry Smith is the protagonist of intracapsular extraction. In the new edition of his book he sets out his technique with much detail and with a wealth of illustrations. He discusses the results obtained and the points of criticism that have arisen. He notes also the recent alternative operations whereby removal of the lens is obtained with the aid of suction pumps and special forceps. There is a most interesting chapter on the old operation of couching; and one of the appendixes is a translation of M. Daviel's original paper in the Memoirs of the Royal Academy of Surgery, Paris, of 1748, done by the late Dr. D. W. Greene of Drayton, Ohio.

DENTITION AS A MEASURE OF MATURITY.

UNDER the direction of Professor Walter F. Dearborn a series of inquiries are being made into the growth of school children in the State of Massachusetts. All former inquiries of this kind have demonstrated that children of exactly the same age, as measured in years, vary widely in stature, weight, epiphyseal formation, mental development, and in tooth eruption. Whatever may be the subject of inquiry—whether mental or tooth development—it is necessary to establish a scale which represents the normal, and, having obtained this standard, then to measure the degree of departure found in any child in terms of months or years. Thus, a child which is 7 years of age by the calendar may have a mentality of 5 years, a stature of 6, a dentition of 7, and an epiphyseal development of 8 years. In the case of tooth eruption many attempts have been made to find a suitable and simple way of establishing a normal scale. Miss Cattell,[1] in dealing statistically with the data gathered from over 11,000 school children between the ages of 5 and 14, has adopted one which has the merit of simplicity. As twenty-eight permanent teeth come into place between the fifth and fourteenth years she divides the process of eruption during that period into twenty-eight stages, each new tooth representing a fresh stage. Seeing that the permanent teeth tend to rise into place in groups of four, one sees theoretical objections to Miss Cattell's proposals, but in practice these objections are not manifest. The one feature which becomes particularly striking in Miss Cattell's results is the extent to which every one of the twenty-eight teeth may vary as to the time it comes into place. The second upper molars are the most regular, and yet they may be in place as early as the end of the tenth year or they may not come into place until the end of the fourteenth year, the norm lying in the twelfth year. The first upper premolars and lateral incisors are most irregular; their appearance ranges over a period of five years. Reckoned on Miss Cattell's scale, tooth eruption in girls moves nearly six months ahead of that of boys. Stated in another way, a girl is "dentally" six months older than a boy of the same calendar age. A racial difference was also observed; in tooth eruption Jewish children moved some months ahead of children of North European descent, while Italian children were as much behind them as the Jews were in front. Many other observations of interest were made: it was found that the time which may elapse between the first appearance of a crown in the gum and its final growth into place is as short as three months in some cases or as long as eighteen months in others. The teeth of the right side have no precedence over those of the left, except in the case of the first upper premolar; that of the right side has often precedence over the left. So far as concerns the main object of Miss Cattell's investigation the result was negative. The point reached by the eruption of the teeth of a child gave no sure index of the physical development—the degree of maturity of its body. Nor was there any close correlation between "dental" age and mental development, but it was found that in "dull normal" children tooth eruption lagged a month or two behind the

[1] *Dentition as a Measure of Maturity.* By Psyche Cattell. Research Associate, Psycho-Educational Clinic, Harvard University. Harvard Monographs in Education, No. 9. Cambridge, Massachusetts: Harvard University Press; London: Milford, Oxford University Press. 1928. (Sup. roy. 8vo, pp. 91; 36 figures. 4s. 6d. net.)

standard of the normal. Miss Cattell's final conclusion, as regards tests for estimating the physical age of a child, is that the old-fashioned "chronological age is probably the best measure of physical maturity that is available."

THE SECRET OPERATION ON PRESIDENT CLEVELAND.

THAT grand old man of surgery Professor W. W. Keen has lately collected into a small volume[1] some half a dozen papers and speeches delivered in the last eleven years. All are of interest, but the first is perhaps the most striking, for it deals with an incident which has been little noticed in England, although it caused great excitement in the United States. The facts are, shortly, as follows. In the year 1893, when Mr. Grover Cleveland was President, the agitation in favour of bimetallism or, as it was popularly called, "free silver," had terminated in the passage of the Sherman Act three years before. The result of this Act and of the "demonetization" of silver in Europe had produced a most alarming financial crisis in the United States. In its repeal lay the only hope of staying the panic, and to secure this the health of the President was vital, for the Vice-President, who would succeed him in case of death or disablement, was "a pronounced silver man." It was in these circumstances that in June, 1893, the medical attendant of Mr. Cleveland discovered evidence of malignant disease of the upper jaw, for which immediate operation was strongly recommended. It was thought that if the public became aware of the condition of the President the effect on the financial situation would be disastrous. Accordingly he went ostensibly for a pleasure cruise on Commodore Benedict's yacht *Oneida*. There, on July 1st, while the vessel steamed slowly up the East River in New York State, the upper jaw, with the exception of the orbital plate, was removed from inside the mouth without external incision, by Dr. Bryant and Professor Keen. After a secondary cauterizing operation the President appeared at the special section of Congress, on August 5th, wearing an artificial palate and upper jaw, and unaltered in appearance and speech. In October the Sherman Act was repealed and all was well. Naturally the disappearance of the President for more than a month excited newspaper comment, and reporters swarmed round his summer villa near Cape Cod. The Secretary of State for War, Colonel Lamont, put them off with the partial truth, that the President was having his teeth attended to and was suffering from rheumatism in his legs; but at the end of August a correspondent of the *Philadelphia Press* published a substantially accurate account of the operation. Dr. Bryant, however, minimized the importance of the operation and conveyed the impression to the reporters that there was no truth in the statement. The unchanged appearance and speech and obvious good health of the President helped the deception, and the correspondent of the Philadelphia paper was branded as "faker," "calamity liar," and other such terms of abuse. It was not till 1917, five years after the death of Mr. Cleveland, that the truth came out in the *Saturday Evening Post* of September 22nd of that year.

AUTUMN MIGRATION OF MOSQUITOS.

IT IS known that, whereas aphides breed parthenogenetically during the summer, at the end of autumn they develop sexual forms which are better able to secure the survival of the species through the winter. Observations lately made in Palestine by Drs. R. Reitler and H. Saliternik, of the Haifa Malaria Research Unit,[2] suggest that mosquitos, which hibernate too, feel the menace of imminent cold weather and leave their breeding places for safer retreats further afield. Whereas, state these observers, the females of *Anopheles clutus* found in Galilee never wander more than two miles from their breeding places in summer, in the late autumn they will travel as far as six miles to find comfortable winter quarters, confident, apparently, that the rains will provide them with breeding places in the spring. Patient observations made in June, August, September, and November of the breeding places, larvae, and imagines found in and about the south-west sector of the "Waters of Merom," which is fringed with marshes and surrounded by a plateau whence ravines five or six miles long lead down to the lake and to the valley of the Jordan which emerges from it, showed that mosquitos, at first frequent in the marshy and ravine regions, decreased in both as the summer progressed. Weekly enumerations made in October showed, however, that the larvae, and later the mosquitos, were increasing near the lake, the rise in the number of imagines spreading next to the ravine villages three miles away, where a distinct increase was recorded on October 18th, a fall on October 25th, and a further rise on November 7th. This rise in number was found to extend even to the village of Rosh Pina, seven miles away on the plateau. It was noted, moreover, that whereas on October 18th males constituted 35 per cent. of the total number of mosquitos studied, on November 7th their proportion was only 15 per cent. By the middle of November larvae were found only by the lake; and imagines, here fewer in number, were more numerous in the ravine villages and on the distant plateau, though no breeding places could be found in their neighbourhood. By this time also the mosquitos had settled themselves more definitely in the village, having left the houses for the cellars and stables, which they prefer as winter quarters. The authors suggest that the autumnal migration occurs in two stages, the earlier swarms including many males, the later the mass of the females. Fertilization, they suggest, may occur early, but the correlated development is delayed till after winter. What causes this migration? It is not due to the action of winds, for though it was measured only in the south-western sector of the lake it was found to occur in others also. During the summer developing ova were found in a majority of 357 dissected females; in 381 examined in October they were rare, but filling the abdominal cavity there was a fatty body whose presence suggested that the insect's driving impulse was no longer reproduction, but for the time being self-preservation. It is noteworthy that if the migrating females are infected with malaria they will, during the autumn, carry the infection further than usual; indeed, in a malarial outbreak which occurred in Rosh Pina a fortnight after the migrating swarm had reached it the mosquitos found to be carrying the infection were the *A. clutus* which had arrived from the lake.

INTER-STATE POST-GRADUATE ASSEMBLY.

AN interesting programme of lectures, clinics, and receptions has been drawn up for the party of American and Canadian members of the Inter-State Post-Graduate Assembly of North America which will visit London on May 27th, 28th, and 29th. The mornings will be occupied by a series of lectures, to be delivered at the House of the Royal Society of Medicine, 1, Wimpole Street, by Sir John Bland-Sutton, Dr. James Collier, Mr. Victor Bonney, Dr. Henry Semon, Sir John Broadbent, Mr. J. E. H. Roberts, Dr. Ronald Canti, Sir William Willcox, Sir W. Arbuthnot Lane, Dr. Donald Hunter, and Mr. Donald Armour. Beginning at 2 p.m. each day demonstrations of cases and operations will be held at various London hospitals. Members of the Assembly and the ladies accompanying them are invited by the director, Mr. Henry S. Wellcome, to a reception which will be held at the Wellcome Historical

[1] *The Surgical Operations on President Cleveland in 1893, together with Six Additional Papers of Reminiscences.* By William W. Keen, M.D. London: J. B. Lippincott Company. 1928. (Demy 12mo, pp. 251. 6s. net.)

[2] *Arch. fur Schiffs- u. Tropen-Hygiene*, vol. xx, 33.3 (March, 1929), p. 170.

Medical Museum on May 28th at 8.30 p.m., and there will be a reception at No. 1, Wimpole Street, on May 29th at 8.30 p.m. By courtesy of the president and the committee of the American Women's Club, all ladies are accorded honorary membership during their stay in London, and a reception will be held on their behalf at the English-Speaking Union on May 28th, at Dartmouth House, 37, Charles Street, W.1, from 4 to 6 p.m.

THE ANNUAL MUSEUM.

THOSE members of the British Medical Association taking part in the sectional work of the Annual Meeting next July who propose to show specimens in the museum are requested to forward a description of their specimens as early as possible, and certainly before the end of May, to the honorary secretaries, Drs. William Susman and H. L. Sheehan, Department of Pathology, The University, York Place, Chorlton-on-Medlock, Manchester.

THE Croonian Lectures before the Royal College of Physicians of London will be given on June 4th, 6th, and 11th by Dr. H. H. Dale, F.R.S., on "Some chemical factors in the control of the circulation."

AMONG those upon whom the University of Glasgow will confer the honorary degree of LL.D. at a graduation ceremony on Wednesday, June 19th, is Dr. C. O. Hawthorne, Chairman of the Representative Body of the British Medical Association.

THE late Lord Rosebery was the only surviving layman, not a member of the Royal Family, to enjoy the distinction of Honorary Fellowship of the Royal College of Surgeons of England, having been elected on July 12th, 1900, the year in which he was appointed a Trustee of the Hunterian Collection.

THE nominations for the new House of Commons were completed on May 21st. In all 1,729 candidates were nominated for 615 seats, this being the largest number of candidates on record. A further "record" was also created by the fact that only in seven instances were candidates returned unopposed. Among the unopposed candidates elected to the new Parliament is Professor Thomas Sinclair, C.B., F.R.C.S., who again represents Queen's University, Belfast. Women candidates number 69, as compared with 27, the previous highest figure. Polling takes place on Thursday, May 30th, and the results will be declared on May 30th and 31st; the new Parliament meets on June 25th.

THE MALCOLM MORRIS LECTURE.

FIFTY YEARS OF DERMATOLOGY.

THE third of the Malcolm Morris Memorial Lectures, forming one of the Chadwick Trust series, was delivered at the House of the Royal Society of Arts on May 16th by Sir NORMAN WALKER, whose subject was the progress of dermatology over half a century. The chairman, Sir STCLAIR THOMSON, introduced the lecturer as one after Malcolm Morris's heart, seeing that he was no "mere specialist," but one who took the widest interest in medicine, and especially in medical education.

Sir NORMAN WALKER, after an expression of gratification at being associated in this remembrance of his old and valued friend, said that Malcolm Morris's connexion with dermatology began about half a century ago, very near to the time when he himself began his medical studies. In those days but little interest was devoted to dermatology in the medical schools of London and Edinburgh. The important progress in this field which had been made since then was to be attributed to several causes working together or separately. Not least among these was the general advance in civilization, housing, and cleanliness; also the better education of the community, the improvement in medical education, the greater degree of specialization, and the co-operation of workers in this branch with those in other branches of medicine. In almost all centres now, said Sir Norman Walker, there was a closer co-ordination between the clinician and the laboratory worker, and the exceptions where such co-ordination did not exist would become fewer as its advantages were appreciated. Still another cause of progress was the institution of inspections of school children, a measure resisted at first in many places by parents and others, but gradually winning in its favour the vast body of public sentiment, especially when the excellent results which followed came to be understood. The lecturer then discussed in turn some of the more familiar diseases, and the steps of progress in regard to each of them. He grouped them into categories, beginning with those in which the cause was definitely known—for example, skin tuberculosis, leprosy, venereal diseases, and fungous diseases, as well as several industrial dermatoses, where the relations between cause and effect were not always so clear. To lupus he devoted a large part of his lecture, describing the frequent scraping and some of the cruder methods of treatment practised in the earlier part of the period which he had taken for his survey. Great hopes arose from the introduction of tuberculin, but when large doses were given severe reactions occurred, and the results were such that only the very stern-hearted could persevere with the treatment, which was abandoned by most of the leading radiologists. The x-ray treatment of lupus at first appeared to offer a very satisfactory means of dealing with these cases, but here, again, dangers and disappointments were revealed, and x rays showed that they could produce delayed effects of a very serious kind. Actinotherapy then presented itself as a very valuable means of treatment, and a satisfactory alternative to the very potent x-ray tube, but it had to be admitted that of the possible late effects of light treatment no more was known to-day than was known of the late effects of x rays at the beginning of this century, and it had been shown that excessive exposure to light was not without its grave dangers. The truth was, said Sir Norman Walker, that although there had been an enormous increase in the armoury of the dermatologist of the present day, many of the new weapons, like x rays, radium, and light, were double-edged, and needed the utmost care and knowledge for their use. After discussing rodent ulcer, and also, in another group, various urticarias and erythemas, of which the cause was still unknown or in dispute, he referred more specifically to Malcolm Morris's work in connexion with several of these conditions, and, in a wider aspect, to his work on venereal diseases, attributing to him much of the credit for the changed and more candid attitude towards that subject.

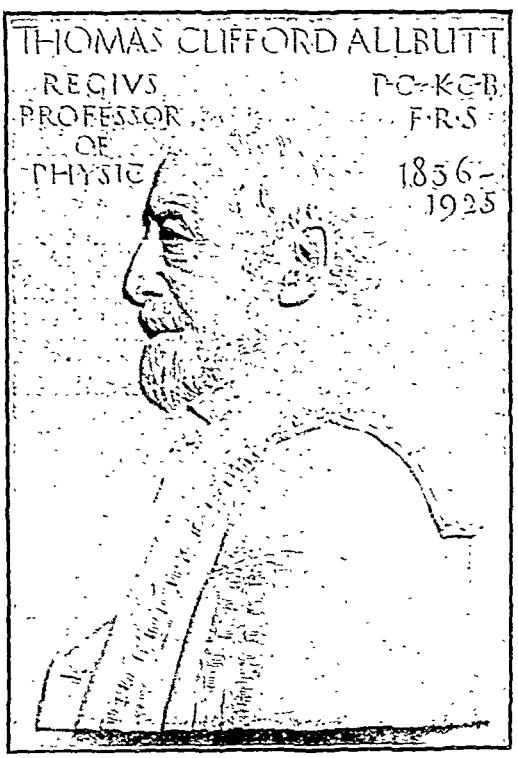
In conclusion, Sir Norman Walker counselled the younger generation not to neglect altogether the old remedies, still less the principles underlying them. Whatever new gifts physics or chemistry or bacteriological science might bring to the dermatologist, it was still a good thing to clean the skin and to give a chance to Nature to do its recuperative work. The dermatologist of the future had a wide field before him, but he must go into it well equipped, trained thoroughly, and able to appreciate the work of experts in every branch.

A vote of thanks to the lecturer was accorded on the proposition of Dr. E. GRAHAM LITTLE, seconded by Sir Malcolm's son, Sir HAROLD MORRIS, K.C.

MEMORIAL TO SIR CLIFFORD ALLBUTT.

UNVEILING CEREMONY AT CAMBRIDGE.

A BRONZE bas-relief portrait in profile of the Rt. Hon. Sir Clifford Allbutt, K.C.B., M.D., F.R.S., Regius Professor of Physic, 1892–1925, and President of the British Medical Association, 1916–1921, has been erected in the Allbutt Library of the Cambridge Medical School. The unveiling ceremony was performed on Saturday, May 18th, by Sir James Crichton-Browne, in the presence of Lady Allbutt and a group of personal friends. A photograph of the plaque is reproduced on this page. The mural tablet is surmounted by the professorial coat of arms, and a small metal plate beneath it records that this portrait is a gift from Lady Allbutt to the Medical School, of which her husband was the head.



Sir HUMPHRY ROLLESTON, Bart., Regius Professor of Physic, in a short introductory speech, said that they were gathered together that afternoon to see unveiled the portrait of a scholar-physician, a great humanist, and a beloved leader, which would be an inspiration to generations of Cambridge men to carry on his traditions. Clifford Allbutt's life pilgrimage fell into three main periods. The first comprised school days at St. Peter's, York, a classical scholarship at Caius College, Cambridge, medical studies at St. George's Hospital, and a year in Paris; the second comprised twenty-eight brilliant years as a consulting physician at Leeds and three years in London; followed by the third and last period of thirty-two years at Cambridge as Regius Professor. They were fortunate to have with them that day a friend whose intimate association with the man whose memory they were honouring began in the middle period, as long ago as 1865. Dr. Crichton-Browne (as he then was), by throwing open to Allbutt the clinical wealth of the West Riding Asylum at Wakefield, helped him in no small degree to build up his great store of knowledge and experience.

Sir JAMES CRICHTON-BROWNE said that he was indeed a contemporary of Clifford Allbutt in the full sense of the word; their friendship lasted without a break for sixty years. Those who knew him in the early days at Leeds foresaw that Allbutt would become the most distinguished and most brilliant physician in this country. His chief title to fame was his work on the circulation—on the heart, the aorta, and blood pressure—and the editing, in association with Sir Humphry Rolleston, of his great *System of Medicine*. Yet Allbutt's early work was not less valuable. It was he who, in 1868, invented the short clinical thermometer now in use, and when a young physician he made ophthalmoscopic observations of fundamental importance to neurological and general medicine. During his busy years in Yorkshire, as hospital physician, clinical observer, and teacher, Allbutt constantly found time to visit the West Riding Asylum, where the speaker had organized the first research laboratory of its kind, and he gave enthusiastic support to every improvement then being effected in the asylum. Later, as Commissioner in Lunacy for three years, he did much to encourage progress in mental hospital administration and the scientific study of insanity. It would be presumptuous, Sir James Crichton-Browne said, for him to praise Clifford Allbutt before a Cambridge audience. He would only recall how zealously Allbutt, as Regius Professor of Physic, promoted those biological studies for which Cambridge was renowned, and how in his academic years he became the great and venerated leader of British medicine. Allbutt in a singular degree combined Yorkshire grit with Southern polish; kindly and gracious, yet a most trenchant critic when occasion required. Sir James Crichton-Browne then asked leave to dispose once and for all of the long-standing legend or fable that Clifford Allbutt was the prototype of Tertius Lydgate in George Eliot's *Middlemarch*, and in drawing a contrast between the two characters and careers—one real, the other fictitious—he touched off some of Sir Clifford's outstanding traits, and paid a charming tribute to his happy married life.

Sir James Crichton-Browne then unveiled the portrait, and remarked on the success with which the artist, Mary G. Gillick, had conveyed the spirit of a great man whom she had never seen; he understood that Mrs. Gillick had taken immense pains to make up for this disadvantage by studying all the portraits and biographies. A many-sided man deserved many kinds of memorial, and it was appropriate that this memorial in a university building should be placed in a room dedicated to the use of books. Clifford Allbutt had always insisted that medicine must be broad based on a liberal education: that *skill without culture was not* enough.

Professor G. H. F. NUTTALL proposed a vote of thanks to Sir James Crichton-Browne for his eloquent and memorable address on a memorable occasion. Clifford Allbutt, he said, was a man so noble that all who knew him could not help but love him. Sir James had once again displayed his wonderful gifts of oratory and the perennial vigour of his mind in this glowing tribute, and they were grateful to their late chief's oldest living friend for his presence and his words that day.

The vote of thanks was accorded with enthusiasm, and Sir JAMES CRICHTON-BROWNE, in a brief acknowledgement, recalled that he himself was now 89, just the age at which Allbutt ended his life of great achievement.

The acting Vice-Chancellor (the Rev. G. A. WEEKES, Master of Sydney) conveyed the thanks of the University to Lady Allbutt for her generous gift of this medallion in memory of a great son of Cambridge, who was not merely the possession of the Medical School, but the pride of the whole University.

Sir HUMPHRY ROLLESTON, replying on Lady Allbutt's behalf, thanked those present for attending, and expressed her gratitude to Professor Nuttall and Dr. W. E. Dixon for arranging the ceremony.

The company included Sir Francis Champneys, Lady Rolleston, Lady Crichton-Browne, Lady Woodhead, Professor H. R. Dean, Master-elect of Trinity Hall, and Mrs. Dean, Professor Barcroft, the Master of Caius and Mrs. Cameron, Dr. and Mrs. W. E. Dixon, Professor Okey, Dr. Louis Cobbett, Dr. C. S. Myers, Dr. G. S. Haynes, Dr. C. G. L. Wolf, and the Editor of the *British Medical Journal*.

Nova et Vetera.

THE SUPPLY OF ANATOMICAL "SUBJECTS."

THE study of practical anatomy as a part of the medical curriculum is of comparatively recent introduction. A real detailed acquaintance with the anatomy of the human body was first made general by the publication of the great work of Vesalius, *De Humani Corporis Fabrica*, in 1543. Before that time anatomy had been studied on animals other than man, but evidence of any acquaintance with human anatomy is scarcely to be found. The Greeks did not dissect, nor, so far as is known, did the Egyptians or Assyrians or any of the other peoples of ancient historical or prehistorical times.

In the two centuries following the death of Vesalius human anatomy was learnt from plates or a smattering attained by attendance on public demonstrations, such as that of the muscles of the forearm so finely depicted by Rembrandt in "The Lesson of Anatomy," now exhibited at The Hague, in which the demonstrator is seen surrounded by earnest students. In England and Scotland demonstrations of the anatomy of the human body were given at rather long intervals by the Company of Barber-Surgeons of London and the Company of Surgeons of Edinburgh. By the Act of Henry VIII, xxii, c. 12, the Company of Barber-Surgeons of London had the right to claim four bodies annually of persons executed for felony. Such a public "anatomy" is shown in the last plate of Hogarth's "Four Stages of Cruelty." Similarly the town council of Edinburgh had, as early as 1505, ordered that there be handed over to the surgeons "anis in the yeir ane condampnit man after he be deid, to make anatomea of, quairthrow we may heif experience, ilk ane to instruct utheris, and we shall do suffrage for the soule." With the body and the soul each thus thoughtfully provided for, the felon's future would seem to have been assured. William Hunter, the founder of the celebrated Windmill Street School of Medicine in London, who died in 1783, described the professors of the most celebrated schools at home and abroad, before his time, as employing in each course of lectures not more than one or at most two subjects, and as demonstrating the performance of the operations of surgery not on human bodies, but on those of brutes. He represented students of medicine and surgery as never exercising themselves in the practice of dissection, because they had no opportunities of so doing. W. Hunter established complete courses of anatomical lectures, and opened a regular school of anatomy where students dissected.

It is obvious that many more bodies than four a year were needed if the medical students of London were to learn their anatomy practically, which, however, was attempted by few of those who afterwards became general practitioners. Those few were driven, in most other countries as well as in Great Britain, to supply themselves from cemeteries and churchyards. Recorded instances of this practice are not many, but they are significant. The well-known Basle physician Felix Platter, who studied at Montpellier at and after 1552, has given an interesting account of how he and some fellow students "resurrected" bodies for dissection. They generally had confederates connected with the cemetery, who helped instead of preventing their activities. At that time there were no means of preserving cadavers during dissection, and a body would only last a few days, so that a comparatively frequent renewal of the supply was necessary. Similar proceedings are on record in other countries. Mr. Henry Lonsdale, in his *Sketch of the Life and Writings of Robert Knox*, the anatomist, says that soon after 1705, when a professor of anatomy had been appointed in Edinburgh to teach the chirurgeon-apothecaries (at a salary of £15 a year), "the supply of subjects was so inadequate that the surgeons' apprentices and young barbers determined upon the adventurous step of procuring them from graveyards." We may add that this practice continued until the Anatomy Act rendered it unnecessary. In 1711 the College of Surgeons in Edinburgh recorded in a minute that "of late there has been a violation of sepulchres in the Greyfriars churchyard, by some who most unchristianly have been stealing, or at least attempting to carry away, the bodies of dead out of their graves." Ten years later they ordered that a clause should be put into the indentures of all apprentices forbidding violation of the churchyards. The iron cages or "mortsafes" still visible in the Greyfriars churchyard bear mute but eloquent witness to the futility of these prohibitions. Sir Robert Christison in his autobiography describes graphically the doings of the exhuming students. At Glasgow things were much the same.

The Select Committee of the House of Commons appointed to inquire into the means of supplying subjects to the schools of anatomy reported in July, 1828. Its chairman was that well-known advocate of medical reform Mr. Henry Warburton, F.R.S., M.P. for Bridport. The evidence put on record in this report was given by a number of well-known surgeons and anatomists, and by some of the most daring and successful resurrection men, or "exhumators," as they are less profanely called in its pages. A former demonstrator at Glasgow told the committee that there the students had to raise subjects: "Every public teacher" (of anatomy) "had what he called his private party; this consisted generally of eight students, and these young gentlemen went out themselves and exhumed the body." No other students had any opportunity of dissection. The English provincial schools were in a like case. Mr. J. B. Estlin of Bristol gave evidence to the effect that "to procure the bodies in a fair state for dissection, young men generally dig them up themselves at the risk of their lives, their health, and their credit in society." There were at that time eight schools in the provinces in which anatomy was taught.

At the end of the eighteenth century no doubt many, if not most, surgeon-apothecaries, having served their apprenticeships and "walked the hospitals," went into practice without having themselves performed dissections, and only a minority of students who were more enthusiastic, or had prospects of obtaining surgical appointments at hospitals, worked at the dissecting table. All this was changed by the passing of the Apothecaries Act of 1815, under which no one was allowed to practise as an apothecary without the licence of the company, which was granted after examination and certification of the candidate's having regularly dissected. At once the demand for subjects was much increased, and the amateur was superseded by the professional resurrectionist or body-snatcher. For a time it seems that subjects were procurable through these men at a moderate price and in sufficient numbers, but as the demand increased, and the risks incurred were also increased by the more stringent enforcement of such laws as were applicable, a deadlock seemed to be in sight. Sir Astley Cooper told the committee that he reckoned that in 1823 there were a thousand students of medicine in London, but that owing to scarcity of subjects many now went abroad, reducing the number to some 800, of whom only 500 actually dissected. The committee reported that:

> "The duration of their studies in London is usually sixteen months, and during that time the number of subjects with which every student of surgery ought to be supplied appears from the evidence (although there is some difference in this point) to be not less than three, two being required for learning the structure of the body and one the mode of operating. The total number of subjects actually dissected in the schools of London in one year is stated to be not greater than from 450 to 500, which is after the rate of less than one subject for each dissecting student; a proportion wholly insufficient for the purposes of complete education."

The Society of Apothecaries had felt compelled to suspend the rule exacting certificates of dissection from candidates. The number of annual certificates thus granted exceeded four hundred.

The report also stated that:

> "When in 1763 Dr. [W.] Hunter proposed to build an anatomical theatre and to endow it with his Museum" (now at Glasgow) "and a salary for a professor, provided the Government would grant him a site of ground for the institution and his late Majesty would extend to it his countenance and protection, he met with a violent refusal. It was therefore only by stealth, and by means not recognized by law, that the teacher was enabled to procure subjects."

Such means were principally disinterment, but, of late, stealing before burial and personation of relatives so as

to obtain unclaimed bodies had occasionally been had recourse to.

The committee seems to have explored all avenues likely to lead to a solution of the problem. Proposals to import bodies openly by agreement with the French authorities were considered, but dismissed as impracticable. Finally, as is well known, the Anatomy Act, which was based upon this report, made it lawful for executors or any person having lawful possession of a body (other than undertakers) to give it up for dissection. Teachers of anatomy were to be licensed. Unfortunately this Act was permissive, and not compulsory. Its framers could not be expected to foresee that some Poor Law guardians and others, instead of as then being only too glad to be relieved of the expenses of burial, would pander to sentiment, and seek easy popularity by refusing to give up unclaimed bodies for dissection.

At the present time the supply of subjects for dissection and the practice of operative surgery in London is quite inadequate. In reply to an inquiry, Professor T. Baillie Johnston of Guy's Hospital Medical School writes as follows:

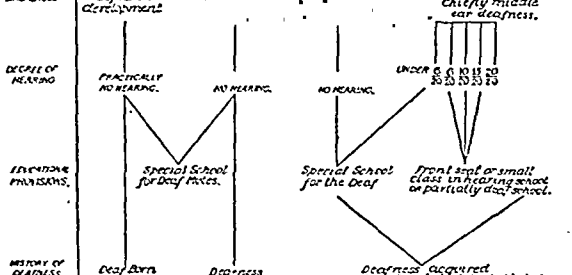
"In London, at the present time, we are getting a sufficient number of bodies to enable all medical students to take part in the dissection of the whole body. Only a small margin is left for classes of operative surgery on the cadaver, which must always take second place in the distribution of subjects. In order to make the number of subjects go round, I have to allocate four students to each abdomen, four students to each head and neck, and two students to each limb.

"As the law stands at the present time, unclaimed bodies *may* be sent to the schools for dissecting purposes, but this involves no legal obligation on the part of boards of guardians, heads of asylums, etc. As a result, partly of prejudice and partly of ignorance, bodies are buried at the expense of the guardians and so lost to the schools. I believe that, if all unclaimed bodies had to be sent to the schools, our supply would be adequate."

E. M. L.

A CLASSIFICATION OF THE DEAF FOR EDUCATIONAL PURPOSES.

THE medical committee of the National Institute for the Deaf has prepared a scheme of classification in order to bring into prominence certain facts in relation to the cause and history of various forms of deafness in children, and so to indicate what educational measures are desirable in any particular case. This scheme, which is illustrated in the form of a diagram, records various degrees of loss of hearing; the normal is represented as a fraction—$\frac{20}{20}$—implying that whispered speech can be heard at a distance



of twenty feet. The various stages of diminished hearing are similarly indicated by fractions up to the point of total deafness, and the most suitable educational treatment is denoted in each case. The committee hopes that this classification will be found useful by medical practitioners, teachers, and others who are concerned with giving advice as to the form of teaching best adapted to the several types of deaf children according to the history and degree of their deprivation of hearing. The office of the National Institute for the Deaf is at 2, Bloomsbury Street, New Oxford Street, W.C.1.

India.

The Calcutta School of Tropical Medicine.

WHEN the Calcutta School of Tropical Medicine opened in 1921 Colonel J. W. D. Megaw, I.M.S., was the first director; in April, 1928, he retired to take up the post of inspector-general of the Punjab civilian hospitals and was followed in the directorship by Lieut.-Colonel H. W. Acton, I.M.S., whose first report has been received. Colonel Acton pays a high tribute to his predecessor for *co-ordinating and encouraging research in the school* and laying sound foundations for future extension. Attention is drawn in the report to the fact that, among other important discoveries made with the assistance of the Indian Research Fund Association, the probable mode of transmission of kala-azar was brought to light at the school by Lieut.-Colonel Knowles, Dr. Napier, and Assistant Surgeon Smith—an observation which was later fully confirmed and extended, *though absolute proof of transmission by* the sandfly is still lacking. The problem is being attacked hopefully from different standpoints, and the diagnostic methods in this disease have been improved. Lieut.-Colonel Chopra, who has been studying the indigenous drugs of India, has shown that many Indian plants are at least as potent as, sometimes more potent than, the corresponding European species; many Indian firms are therefore using them instead of importing. He has also been able to *suggest the employment of certain indigenous drugs, similar* in action to those imported, but less expensive. Spirochaetosis is being investigated by Lieut.-Colonel Knowles with a view to determining why a disease, such as relapsing fever, occurs only at certain times of the year. He has obtained a considerable amount of information about the changes in morphology which spirochaetes undergo in the transmitting insect. Dr. J. P. Bose, in conjunction with the director of the Calcutta School, has obtained evidence that differences in potency of the same sample of insulin depend on the coloration of animals. Work on similar lines is being continued in human beings who show an increased or diminished output of adrenaline. Colonel Acton has also prepared a large collection of illustrations of the various parasitic fungi which grow in the skin; he hopes that it may be published eventually as an atlas. He comments on the relations of clinical research and medical treatment, and mentions how it was originally found necessary to open special out-patient departments in the school in order to obtain a sufficient supply of clinical material. This has now resulted in the staff being kept so occupied with clinical work that they are being seriously handicapped in carrying on research; numerous inquiries are also received daily on a large variety of medical subjects. The extent of the services rendered by the Calcutta School of Tropical Medicine, with which is incorporated the Carmichael Hospital for Tropical Diseases, can be appreciated from these brief references to an interesting report.

Cholera in Bombay.

A severe epidemic of cholera prevailed in the Presidency of Bombay from March to November, 1927, and resulted in over 26,000 deaths. In the years 1925 and 1926 there were 57 and 73 deaths respectively from this cause, and an outbreak comparable with that in 1927 has not occurred since 1919, when more than 50,000 deaths were reported. Previous bad cholera years were: 1912 (with over 64,000 deaths); 1909 (28,000), 1906 (46,000), and 1900 (163,000). The disease appeared to have died out after 1924, but it was noticed that the cases reported in the two subsequent years were not limited to any one part of the Presidency, and therefore the danger was obviously still generally present. In his report for 1927 Lieut.-Colonel H. Melhuish, director of public health for the Presidency of Bombay, comments upon these facts, and adds that there was a scarcity of water in many of the most affected areas, as a result of the failure of the late monsoon of 1926. He remarks that this epidemic has gone far to confirm the theory enunciated by Sir Leonard Rogers, which bases the recrudescence of cholera epidemics on the following factors: an absolute humidity figure of less than 0.4; scarcity of water,

owing to failure of the preceding late rains; freedom from outbreaks during the preceding years; and fairs and pilgrimages. Colonel Melhuish states that the absolute humidity figure in the Deccan and Karnatak—the two most seriously affected areas—was in agreement after the month of March with the standard fixed by Sir Leonard Rogers; the fairs common at that time of the year seem also to have played their part in several of the local outbreaks. The heaviest incidence of cholera was in the southern registration district, the central being the next most affected. Active preventive measures were taken from the first manifestation of the epidemic; voluntary cholera committees were formed to promote prophylaxis and treatment in all districts, and educational leaflets were distributed. All the wells were treated with potassium permanganate, and, in the absence of other disinfectants, lime was used with success in many places.

Kashmir Mission Hospital.

The problems raised by the increasing prevalence of tuberculosis in Kashmir have been mentioned previously in these columns. The bovine, or surgical, type has always been common, and in the annual report of the Church Missionary Society's Hospital in that city for 1928 it is stated that sometimes nearly a quarter of the cases in the wards are due to the infection. Pulmonary tuberculosis was, however, almost unknown there until 1890, but during the last two decades it has been extending very rapidly; this is probably attributable to the better facilities for travel, which are popularizing Kashmir as a summer resort for consumptives in all stages of the disease. In 1912 Dr. E. F. Neve, medical superintendent of the hospital, urged the adoption by the Kashmir State authorities of vigorous anti-tuberculosis measures, including the provision of a hospital for advanced cases and a sanatorium for patients in the early stages. Up to the present, however, no active steps have been taken in this respect, and, owing to the poor sanitation in this populous centre, the disease is being enabled to spread. The mission hospital serves a population of 142,000 city dwellers, and six or seven times this number of the rural population. Open-air treatment has been practised for the past forty years, since for nine months each year the beds of patients can remain out on the broad verandahs. The value of fresh air and sunlight has been marked, not only as regards tuberculous patients, but also in medical and surgical cases of all kinds. Dr. Neve comments that there appears, therefore, to be little need in Kashmir for the ultra-violet apparatus. He expresses his deep regret that the leper hospital founded by him thirty-six years ago has now been transferred compulsorily to the State authorities. We mentioned two years ago the excellent work of this institution, and since then a home has been provided for the segregation of the healthy children of lepers; this remains under Dr. Neve's control. It is stated in the report that although cancer—apart from the kangri-burn type—is rare, there is some evidence in support of the view that carcinoma is due to the overgrowth of tissues which, owing to continued irritation, have escaped from the controlling influence of the trophic nerves. As in his previous reports, Dr. Neve includes interesting details of his work in the surrounding country districts, and in the present issue there are good photographs of the Mission Hospital and its surroundings.

Scotland.

Autumn Post-Graduate Course in Glasgow.

As in previous years the Glasgow Post-Graduate Medical Association has arranged a special course of instruction in that city during the last two weeks in August and the first fortnight of September. The mornings will be devoted to general medicine, surgical diagnosis, and minor surgery, lectures and demonstrations being provided in the Victoria Infirmary and the Western Infirmary. In the afternoons teaching in special subjects will be provided at various special hospitals and the special departments of general hospitals. A syllabus has been issued in connexion with this course, and may be obtained from Dr. James Carslaw, the secretary of the Glasgow Post-Graduate Medical Association, 9, Woodside Terrace, Glasgow, C.3. Some clinical assistantships are available in a number of the hospitals during the summer months as well as at other times in the year. Graduates desiring to take advantage of these appointments are advised to enrol for a period of three months, and to devote to the work either the whole or part of the day according to the terms of the particular clinical assistantship; graduates with less time at their disposal may, however, be accepted for shorter periods. Further information with regard to these assistantships may be obtained from Dr. Carslaw.

New Department of Zoology at Edinburgh University.

Prince George visited Edinburgh on May 15th and opened the new Department of Zoology, which has been erected by the University of Edinburgh at the King's Buildings. The Natural History Department, in which the teaching of zoology has hitherto been carried on, forms part of the old college. For many years the premises have been wholly inadequate to meet the needs of the students and of the post-graduate workers in the department. In addition to providing instruction for science students extending over four years, and for medical students in their final year, the work of the department includes post-graduate courses in medical entomology, protozoology, and helminthology for the diplomas in tropical medicine and public health. The history of the new department began with the sympathetic interest of the late Mr. Laurence Pullar, LL.D., of Bridge of Earn. Since the early seventies Mr. Pullar had been keenly interested in marine zoology, particularly in those aspects of the subject investigated by his friend the late Sir John Murray. In 1923 Mr. Pullar visited the old college, and the adverse conditions under which teaching and research were being carried on made such a deep impression on him that shortly afterwards he offered a sum of £20,000 towards the erection of a new department, stipulating that it should be considered as from an anonymous donor. In 1926 the Trustees of the Carnegie Trust for the Universities of Scotland set aside a sum of £18,000 for the same purpose. Later in the same year all doubts as to the adequacy of the money in hand were set at rest by the munificent gift of £74,000 by the International Education Board, founded by Mr. John D. Rockefeller, jun., in 1923. The co-operation of the representative of the board, Professor Augustus Trowbridge of Princeton University, did much to make this very generous gift possible. Work on the site at King's Buildings was begun in June, 1927, the architects being Sir Robert Lorimer and Mr. John F. Matthew. The building, of sandstone from Blaxter quarry in Northumberland, consists of a central part and two wings. The panels between the windows of the ground and first floors in both wings bear oval medallions of animal subjects representative of the principal zoogeographical regions; these medallions were modelled in clay by Miss Phyllis Bone, and subsequently cast in concrete, and they add greatly to the attractiveness of the frontage. "Fitness for purpose" has been the keynote of the design throughout. A special feature is the lighting of the building; the depth has been restricted so that the rooms on each side of the central corridor receive ample light. The laboratories and research rooms face north or north-east, and their exceptionally large windows extend from bench-level to the ceiling. The cupola of the museum has been provided with a special glass, which excludes the ultra-violet rays and so diminishes the fading of the colours of the specimens. At the same time it disturbs colour values to a very slight degree, and diffuses the light in such a manner as to make blinds unnecessary. The production of this glass has been the result of consultation between Sir Herbert Jackson, F.R.S., and Messrs. Chance of Birmingham. On the ground floor is a room for aquaria and vivaria, equipped with an automatic pump for supplying compressed air to the aquaria. The Vice-Chancellor of the University, Sir Alfred Ewing, who presided at the opening ceremony, remarked that the chair of the subject in Edinburgh dated from 1770. In his own student days the professor was Wyville Thomson of *Challenger* fame, the professor was Wyville Thomson of *Challenger* fame. His successor was Professor Cossar Ewart, still happily with them, who in turn was succeeded by the present holder, Professor J. H. Ashworth. It was mainly to the reputation as a scientific worker, to the personality, and to the

unsparing efforts of Professor Ashworth that they owed the gifts which had enabled them to erect that building. The new Institute of Zoology was the second of "The King's Buildings," an extension of the University which was already closely associated with the Royal House. The foundation of the first of these buildings, the department of chemistry, was laid nine years ago by the King; it was opened by His Royal Highness the Prince of Wales in 1924. It was with particular pleasure that he invited another representative of the Royal Family to perform the same ceremonial office for the new building, which was soon to be followed, they confidently hoped, by a series of others. After Prince George had declared the building officially open, he accepted the honorary degree of Doctor of Laws, the capping ceremony being performed by the Vice-Chancellor. The new extension of the University occupies an open site on the southern outskirts of the city to the east of Blackford Hill. It is a source of gratification that the building has been completed in time to allow of its official opening before the retirement of the Vice-Chancellor at the end of the present term. He thus leaves the extension scheme, for the inception of which he was responsible, in an advanced state of development.

Royal Edinburgh Hospital for Sick Children.

The seventieth annual general meeting of contributors to the Royal Edinburgh Hospital for Sick Children was held on May 15th. Mr. Colin M. Black, chairman of directors, who presided, reported that the ordinary income had fallen short of the expenditure incurred in the hospital and convalescent home by £8,107, and that this sum had to be found from legacies and special donations. The average daily number of patients treated during 1928 was 117, and the average duration of residence 17.3 days. The total number of in-patients was 2,762, and of attendances at the various sections of the out-patient department 33,833. More than half of the in-patients came from outside the area of the city. In the hospital 1,065 operations were performed, and in the out-patient department 1,852 minor operations. In the medical part of the report it is stated that 37 per cent. of the in-patients were aged 2 years or under, and that 72 per cent. of the total deaths (which numbered 265) occurred during the same age period. The frequency and heavy death rate of pneumonia in young children in the Edinburgh area is commented upon. During 1928, 284 cases of pneumonia and its complications, 50 of them fatal, passed through the wards. Tuberculosis accounted for about 11 per cent. of the total admissions. Stress is laid upon the very satisfactory results which have followed the adoption some years ago by the surgical staff of the tannic acid method of treatment of burns; only 5 out of 58 admissions for burns in 1928 proved fatal. The chairman intimated that a new ward for ear, nose, and throat cases was almost ready for occupation.

Inverness Hospital Extension.

The laying of the foundation stone of the reconstructed Northern Hospital at Inverness by Dr. Walter E. Elliot, Under Secretary of State for Scotland, was reported in the *British Medical Journal* on May 19th, 1928 (p. 872). Almost exactly a year later, on May 17th, the Duke of York, accompanied by the Duchess, performed the opening ceremony of the children's wing of the new infirmary. The Duke and Duchess, who also bear the titles of Earl and Countess of Inverness, received a great ovation from a crowd, which must have numbered 30,000, drawn from all parts of the Highlands. The Mackintosh of Mackintosh, chairman of directors, presided. Provost Macewen welcomed the Royal visitors, and said that the Northern Infirmary was not primarily an Inverness hospital, but a hospital for the whole of the Northern Highlands. There were many people living in isolated districts who were too poor or too ill to undertake the long journey to one of the larger centres, and for these the enlarged hospital would prove a very great boon. After the Duke had declared the new children's unit open, the Duchess of York named the main ward "The Princess Elizabeth of York Ward." Lord Lovat expressed the great appreciation of the people of the North of the auspicious start given by their Royal Highnesses to the new hospital, which developments, in connexion with the recent Local Government (Scotland) Act, were likely to make increasingly important.

England and Wales.

Health and Industry.

THE report for the year 1928 of the Industrial Health Education Society indicates an increasing tendency on the part of the workers to avail themselves of the help the society has to offer them. During the year the society received requests for 398 health talks, an increase of 115 over the number in 1927. Sometimes groups of workers have asked for as many as two, three, or even five separate lectures, each relating to a different health subject. This year the council has for the first time entered Wales, and its work, made possible by a grant of £500 from the Miners Welfare Committee, and of £250 from the Carnegie Trust, has grown rapidly in the mining villages. The Central Miners Welfare Committee has offered £500 to enable the council to conduct a campaign in seventeen mining areas where the society so far has not given any health talks. There has been a great demand from workers in building trades, in the iron and steel trades, and from a number of national health insurance committees, for the leaflet prepared by Professor Collis. Dr. Prosser White's pamphlet on mule-spinner's cancer has also been in great demand among the cotton spinners in Lancashire and Yorkshire. The leaflet on health hints to miners, prepared by Sir Thomas Oliver and Professor Collis, has been distributed free whenever engagements among miners were held. Further important extensions of the society's work have been the introduction of health films, so far only in mining centres, and the creation of a women's committee for the purpose of arranging health talks with women workers in the London area. The finances of the society, however, are not keeping pace with the developments of its work, and the council hopes that employers will support the society in its propaganda and in the endeavour to increase the strength and efficiency of the worker.

Royal Sanitary Institute Congress.

The preliminary programme of the fortieth congress of the Royal Sanitary Institute, which is to be held at Sheffield from July 13th to 20th, has now been issued. The president of the congress, Earl Fitzwilliam, will deliver his inaugural address on Monday, July 15th. Sir Allan Powell will lecture on some aspects of the food problem, and Professor W. W. Jameson will give the popular lecture. In all, 750 delegates have been appointed by 430 authorities at home and abroad. Among the subjects arranged for discussion are: mental hygiene of the child and of the adult; maternity and child welfare services; the Local Government Act and how it will affect these services; cremation; health education; national health insurance services; hospital and convalescent treatment and after-care; food hygiene; industrial welfare; smoke abatement; housing and regional planning; rivers pollution; refuse disposal; main drainage; water supply. The Lord Mayor of Sheffield is the chairman of the local committee, and the town clerk and the medical officer of health, Professor F. E. Wynne, are joint honorary local secretaries.

Chailey Heritage Hospitals.

Dr. G. Murray Levick has published an illustrated report of the experimental treatment of marasmic babies at the hospitals in connexion with the Heritage Craft Schools, Chailey. The general principle underlying his system includes some modification of the usual therapeutic measures in such cases. The infants were nursed in the open air from the time of their arrival, so as to promote sensory stimulation of the skin and ensure the preservation of atmospheric humidity in the inbreathed air. Each child was fed on the diet that it had been receiving before admission during the first three days in hospital, while it was being acclimatized to its new surroundings; then, in every case, unheated and non-citrated cow's milk was given, thus preserving the vitamin C. The necessary iron was supplied by green vegetables cooked for a short time in as little water as possible, and with marmite. In the case of very young and debilitated infants artificial light treatment was administered from the first, due care being taken to establish tolerance; otherwise natural sunlight,

whenever available, was utilized in preference to artificial radiation. In this connexion Dr. Murray Levick comments on the danger of placing treatment by artificial light in unskilled hands, particularly in the case of very young infants, whose tissues are delicate and relatively translucent. Very rapid and satisfactory progress is said to have resulted in all cases treated at Chailey by this combination of moving undried air, dieting, and artificial light.

Salford Venereal Diseases Treatment Scheme.

The report for the year 1928 of the venereal diseases scheme of the City of Salford deals only with the last nine months of the year, as it was not until April 1st that the municipal clinic came into existence and a venereal diseases medical officer took up his official duties. These arrangements differed so much from those hitherto existing that on April 1st practically a new venereal diseases scheme was created in Salford. In the report, which is signed by Colonel E. T. Burke, venereal diseases medical officer, an assessment is made of the number of infected persons in Salford based upon the estimated prevalence of the venereal diseases in England and Wales. On the assumption that 14 per cent. of the total population is venereally infected, it is calculated that there are at least 30,000 persons in Salford suffering from syphilis and gonorrhœa, 1,000 fresh infections occurring each year, with a mortality from syphilis of at least 200. The economic loss from venereal disease may be realized from the fact that whereas the average duration of disablement from all diseases of members of approved societies is 7.2 weeks, the average disablement from venereal diseases is 19.9 weeks. These striking figures are rightly held to justify the expenditure of £5,600, which was the estimated gross cost of the clinic during the first year of its working. The new municipal clinic differs from the superseded treatment centre held in the out-patient department of Salford Royal Infirmary in the following important respects: it has a whole-time staff; a clinical director, responsible to the medical officer of health, to co-ordinate the work of the department; and treatment is given in premises specially equipped for venereal disease work alone for no less than seventy-one and a half hours weekly for each sex, a far longer period than was devoted to this end at the Salford Royal Infirmary. The main principle upon which the clinic is organized is that the unit to be treated is not the individual, but the family; thus every effort is made to get the patients and other members of the family of a child suffering from venereal disease to attend for examination and, if necessary, for treatment. In the case of extra-marital infection, the patient is asked to persuade the party alleged to have conveyed the infection to come for examination. So successful has been the organization employed that during its nine months of working the clinic has dealt with more new patients and has registered more attendances than any other treatment centre covering a similar size of population. When it was proposed to move the treatment centre from the hospital to the clinic it was objected that unless a clinic is attached to hospital premises patients will refuse to come to it. In point of fact, whereas the average annual number of new cases attending for treatment at the hospital centre during the period 1919-27 was 795, the number attending the clinic during the nine months of its working was 1,220. The difference between the numbers of intermediate attendances is even more striking, being 5,719 in the former and 26,155 in the latter. The average number of attendances per patient attending the clinic, calculated as total attendances divided by the number of new patients, has been 39.3, or, including non-venereal cases, 29.1. During the period under review there have been 433 defaulters, representing 30 per cent. of new patients. To deal with the serious social problem created by these individuals, the clinic sent out follow-up letters, in response to which 116 of the patients returned and still attend, ten returned for a period only, six returned and were transferred, and twenty-eight returned and were discharged. In Colonel Burke's view the question of compulsory treatment is one which must soon claim the attention of all local authorities, who at present provide a great deal of money which is being wasted by the defaulter. He deplores the fact that more advantage is not taken of the valuable clinical material at the clinic by those who are in general practice, and suggests that it would be to the interest of both patient and practitioner if the latter would occasionally take a course of instruction at the clinic, so as to keep himself abreast of recent methods of investigation and treatment.

Correspondence.

THE DISTRIBUTION OF RADIUM.

SIR,—In your issue of May 11th there appear two letters dealing with the distribution of radium for the treatment of cancer. In reading this and other correspondence one is struck by the exclusive use of the word "surgeons" as indicating those who should be in control of future supplies. I agree, of course, with Mr. Duncan Fitzwilliams when he deplores the haphazard way in which radium is sometimes obtained and applied by practitioners who have no experience whatever of this form of treatment; but it appears to me strange that the professional radiologist, who has borne the burden and heat of the day, and who upheld the use of radium when most surgeons opposed it, should now be ignored. It is not many years since I heard a surgeon, now prominent as an advocate of radium, publicly classify *x* rays and radium in malignant disease with the violet leaf poultices, *et hoc genus omne*, of the herbalist "cancer-curer."

For a quarter of a century those in charge of the *x*-ray departments of the large general hospitals have been coping with a never-ending stream of inoperable and recurrent cancer cases. Snowed under with masses of the most unpromising material, they have nevertheless striven with success to relieve pain and prevent or mitigate external ulceration; and in certain cases—relatively few, but in the aggregate, considerable in number—have restored to active life the apparently incurable. Nor is there any sign of lessening of the flood, nor likelihood of its abatement in the immediate future. If the radiologists in charge of such departments have an experience of radium which is small compared with their knowledge of *x* rays, this is due to no fault of theirs, but to the cost and scarcity of this therapeutic agent. It can scarcely be denied that *x*-ray therapy departments should be liberally dealt with in the allocation of any public supplies of radium. There must be many radiologists in this country who, in the past ten years, have treated, not hundreds, but thousands of cancer cases; and these almost all of advanced type—an experience which cannot be paralleled by any other class of worker.

The medical public should not be led to believe that the present surgical methods of using radium represent a final stage of technique. While they will always be used to some extent, they are in great measure a compromise. They represent in many cases the best possible procedure with the amounts of radium at our disposal. But already in France and Belgium their limitations are being recognized. Dr. Régaud, director of the Paris Radium Institute, has pointed out that radium therapy at a distance is the ideal to be aimed at. He recognizes that this is a return to the technique of deep *x*-ray therapy, and expresses the opinion that it is impossible to say at the present time whether gamma ray treatment will in future be given by large quantities of radium used at a distance of 15 cm. or more from the skin, or by *x*-ray tubes excited by currents of the order of 2,000,000 volts.

In attempting to envisage their respective possibilities, it should be remembered that the present value of the radium necessary for such "distance treatment" is between £50,000 and £75,000 in a single "bomb." On the other hand, experimental *x*-ray tubes have already been constructed to withstand over a million volts. It is therefore probable that, ultimately, the choice between naturally or artificially produced gamma rays will be determined by financial considerations only. But while this is true as between such super-*x* rays and gamma rays from radium

element, the former would have the advantage over "radon" for constancy of output. As pointed out by Mr. R. K. White, it is quite unjustifiable to assume that, where long exposures are concerned, the therapeutic effects of radon and radium element are in all respects similar, although the mathematical expressions representing a given dosage may be identical.—I am, etc.,

London, W.1, May 15th. F. HERNAMAN-JOHNSON.

CATARRHAL VACCINES.

SIR,—You have allowed me to record in the *Journal* during the last few years some statistics relating to the use of vaccines against colds and catarrhs in a public school, and the following figures obtained last Easter term may be of interest to some. The total number of boys concerned was 525; of these 148 (28 per cent.) were inoculated, and 377 (72 per cent.) were not.

	Inoculated.	Not Inoculated.
Colds reported (out-patients, 193)	45 (30%)	148 (32%)
Influenza, feverish chills (in-patients, 256)	56 (37%)	200 (52%)
Average days lost	9.5	10.2
Second attacks or relapses	7 (4.7%)	20 (5.3%)
Complications	10 (18%)	60 (30%)

Analysis of the complications shows that all the serious cases were among the non-inoculated—for example: 4 cases of frontal sinusitis; 8 of cervical adenitis (including 2 abscesses with operation); 10 of acute otitis (including 2 mastoid operations); 1 of lobar pneumonia; and 5 of myocarditis. None of the inoculated boys suffered from severe complications, though two were incapacitated for some time by subsequent debility.

In addition to the usual circular to parents, sent out at the end of December, special letters were written to the parents of known susceptible boys urging the use of vaccines, but in only 10 cases was this form of protection adopted; of these, 2 were affected with influenza, referred to in the paragraph above. Of the remaining 20 who were not inoculated 15 were affected, 9 of them severely, with complications.

Parke Davis's anticatarrhal vaccine was generally used—two-thirds of the administration during the Christmas holidays, one-third at the beginning of the Easter term. Three doses were given as a rule, 0.25, 0.5, and 1 c.cm., irrespective of age or weight. (In previous years rather smaller doses were given to the younger boys.) In no case was there any reaction of importance, a slightly sore arm for twenty-four hours being the worst.

In this continued attempt to estimate the value of preventive inoculation against endemic catarrh it is unfortunate that epidemic influenza, and of a severe type, should have again appeared, since I am not of the opinion that this latter is affected by the vaccine used. However, the figures given seem to show once more a slight but definite advantage in favour of the inoculated, both as regards the number affected and more particularly as regards the number and severity of the complications.

It will be noted that only 28 per cent. availed themselves of this method of protection—less than in previous years—and it is evident that the majority of parents of this class are not convinced of the value of vaccines or even prepared to give them a trial. It must be admitted that there is no overwhelming evidence in its favour, judging by mere numbers, though from a knowledge of the individuals concerned I am convinced that there is a very definite advantage.

But if, as I believe, the main safeguard against endemic catarrh lies in vaccines, it must be admitted that finality is not reached by the present methods, and the results are not good enough to convince the sceptic. It may be that the preparation and the dose (in number, amount, and time) may be improved. Compulsion is not practical politics, and it is useless to advocate wholesale inoculation to parents during the September term, when good health is the rule.

My own view is that the results, though far from perfect, are more than good enough to justify continued effort, particularly in the cases of the known susceptibles to catarrhal infection.—I am, etc.,

L. R. LEMPRIERE,
May 14th. Medical Officer, Haileybury College.

"YEAST AND PUFFERY."

SIR,—Referring to your article under the above heading in the *Journal* of April 27th, 1929 (p. 780), it may interest and amaze your readers to hear of my experience with reference to the advertising of yeast.

On April 3rd of last year my secretary made an appointment for me to see a Miss E. She duly appeared, not, however, in the guise of a patient, but in that of an advertising agent for a well-known brand of yeast. Her proposition to me, made most charmingly, but in the best American business manner, was that I should write a testimonial extolling the virtues of yeast, this testimonial, together with my name and photograph, to appear in magazines, newspapers, and (or) in other advertising media published in the United States of America and Canada.

For doing this I was to receive the sum of £150. To quiet any scruples I might have against so doing, I was informed that four members of my profession in London had already signed the agreement, a copy of which is here appended. The confiding lady even informed me what each of them had told her they proposed to do with this money so nobly earned!

I hope that it is scarcely necessary to add that, while showing her the door, I replied to her importunities by saying that there were things in this life that I valued more than one hundred and fifty pounds, and that they were my own self-respect and the respect of my fellow members of the medical profession.—I am, etc.,

London, W.1, May 14th. DONALD ARMOUR.

Date
Address
City

In consideration of the sum of £150, receipt whereof is hereby acknowledged, I hereby give permission to the —— Company to use, in the advertising of ——'s yeast in magazines, newspapers, and (or) in other advertising media, published in the United States of America and Canada, my name, photograph, and (or) the letter I have submitted, or any part thereof.

It is understood that the —— Company is in no way obliged to use any of the material covered by this release.

WHAT IS STELLWAG'S SIGN?

SIR,—In an article on early Graves's disease by Dr. Hannan in your issue of May 11th (p. 848), stress is laid on the importance of Stellwag's sign, which is defined as "widening of the palpebral fissure caused by a spasmodic retraction of the upper eyelids."

The sign is thus defined in most of the current textbooks, notably Osler, Taylor (Poulton), Conybeare, Tidy's *Synopsis*, as well as in Purves-Stewart's *Diagnosis of Nervous Diseases*, and Campbell Thomson's *Diseases of the Nervous System*. On the other hand, in Price's textbook it is described as infrequent and incomplete blinking; in Osler and McCrae's *System*, as staring with a diminished frequency of reflex winking; and in Allbutt and Rolleston's *System*, as "retraction of lids and consequent widening of the palpebral slit, with which is associated infrequency and incompleteness of nictitation."

Finally, in Swanzy's *Diseases of the Eye* (edited by Werner) Stellwag's sign is given as "incompleteness and diminished frequency of the act of involuntary nictitation"; "an abnormal widening of the palpebral fissure" is described as Dalrymple's sign, and it is stated that this sign is often erroneously attributed to Stellwag or included in his sign. The same distinction between Stellwag's and Dalrymple's signs is made in three other textbooks on the eye which I have been able to consult.

Although the eye signs of Graves's disease are largely of academic interest they have become one of the traditions of medicine and are taught to successive generations of students; and uniformity in their nomenclature is therefore desirable.—I am, etc.,

Oxford, May 20th. W. T. COLLIER.

CHRONIC DEAFNESS.

SIR,—Your leader on chronic deafness in the issue of May 11th (p. 864) has drawn attention to what is indeed a change of heart. Only two years ago, at the Royal Society of Medicine, it was boldly stated, with little numerical opposition, that chronic middle-ear deafness was non-existent, that there was only one form of chronic deafness—namely, oto-sclerosis—and that this was incurable. Removal of the tonsils and nasal septum, even when advisable on general surgical principles, as a means of improvement of deafness, was scouted and stated to be almost immoral, and the results of treatment, although evidence to the contrary was produced, were treated with scepticism.

There is now, however, reason for caution lest the pendulum swing too much the other way. For oto-sclerosis which has become definitely established there is still no cure, and from its pathology it is difficult to see how there can be. Its prevention is another matter, and constitutional treatment would appear to hold out some hope. Oto-sclerosis is not, however, by any means the chief cause of chronic deafness, the common one being a pure middle-ear deafness predisposed to by septic infection of the tympanum and deformities of the nose; and the essential objects of treatment—not at all founded on empiricism, but on a logical pathological hypothesis—are to induce reabsorption of the products of chronic inflammation in the middle ear, and re-educate the dormant centre of hearing. As a preliminary all septic foci must be removed and deformities rectified. I have advocated and practised treatment for these purposes for the past eight years, and was able to report at the meeting to which you refer that 96 per cent. in a series of recent cases, not specially selected, were cured or greatly relieved.

I do not think any real difficulty exists as to testing hearing for practical purposes. The important thing for the patient is that he is cut off from the amenities of life by his deafness, and if, after treatment, he can join in conversation and listen to a sermon, concert, or play, then from his standpoint he is greatly improved or cured. It is comparatively unimportant whether he can hear a watch tick well or a tuning-fork hum correctly, and he is not interested in the niceties of the audiometer, however interesting or valuable it may be from an academic or investigation standpoint.—I am, etc.,

Bath, May 16th. H. NORMAN BARNETT.

IMMEDIATE ENUCLEATION FOR QUINSY.

SIR,—For twenty-five years I have performed this operation in peritonsillitis, and during my period of service as laryngologist at the Melbourne Hospital, the Children's Hospital, and St. Vincent's I have operated on many hundreds of patients with unvarying success. I always strip up the anterior pillar from below with an elevator, as figured in Dr. Dan McKenzie's book. It is nearly always free from adhesions at this point.

Mr. R. Wallace's method of "finger" enucleation[1] causes too much unnecessary bruising. In my opinion it is not necessary to wait three or four days, as advised by Mr. Wallace. At the first sign of oedema operate and save your patient days of agony or discomfort. As regards local anaesthesia in tonsillectomy I gave it up more than ten years ago because I found secondary haemorrhage was not a rare sequel.

For the past twelve months I have been treating all adults with diathermy, and I never use any other method excepting in cases of peritonsillitis. At first I used the monopolar method, but with more experience I have adopted the bipolar method. Using a weak voltage and a high frequency and placing the large indifferent electrode on the calf of the patient, no severe reaction will follow; the important point is not to attempt too much at a time. The active terminal is a blunt needle, and if there are definite septic foci I bury the needle in these to begin with. In adults with septic manifestations it may be sufficient to destroy these without completely removing the tonsil. As diathermy machines vary so much it would be as well to try the effect on a piece of raw steak and estimate that the effect on a tonsil would be twice as great. In the thirteen months only two patients have missed a meal. The number of treatments varies according to the tonsil, the patient, and the effectiveness of local anaesthesia. I always use Wyatt Wingrave's formula. The interval between treatments is at least a week, sometimes three weeks.—I am, etc.,

Melbourne, April 4th. W. KENT HUGHES.

[1] *British Medical Journal*, February 16th, 1929, p. 296.

HOSPITAL RADIOLOGICAL SERVICES.

SIR,—It appears to me as a practising radiologist that the Council of the British Medical Association is to be heartily congratulated and thanked by radiologists for Appendix X of the Annual Report relating to hospital radiological services (*Supplement*, April 20th, 1929, p. 129), and, in the interests of the private radiologists, widest attention should be drawn to this memorandum.

As a radiologist whose fees are determined according to the potentialities of the district of the practice, I have felt the very unfair competition of hospital radiology, the overhead charges of which are invariably borne by the charitable side of the hospital, which also has the advantage of benevolent local rates, while the private radiologist is heavily rated at normal rates.

An erroneous view appears to exist that it is cheaper if the patient is sent as a paying patient to a hospital than if sent to a private radiologist. This view is fostered by the circulars sent out by hospitals soliciting private *x*-ray work. For example, one before me states, "These facilities will only be available for patients who are not eligible for hospital benefit and who are unable to pay the fees of a private radiologist." As the list of fees given range up to six guineas many private radiologists would be quite willing to cater for such patients.

The incorrectness of a plea of cheapness is at once seen by a comparison of my own private fees with those taken from the scale of fees from two local hospitals and the hospital which broadcasts the circular mentioned above. The fees are in guineas:

	Private Fee.	Hospital I.	Hospital II.	Hospital III.
Wrist or hand	1	1½	1-2	1½
Ankle or knee	1	1½	1-2	1½
Thorax screen and film .	2	2	2-3	2
Screen examination for foreign body	½	1	Not given	Not given
Barium meal	5-7	5	4-6	5
Urinary tract	2-3	3	2-3	2-3
Bladder	1	1½	Not given	1½
Foot	1	1½	1-2	1½
Cervical spine	2	2	1½-2½	2
Skull	2	2	2½	2
Barium enema	2-3	3	2-3	3
Oesophagus	1-1½	2	2-3	2

The only instance in which the hospitals' fee is lower is in that of a barium meal. I have seen an example of a barium meal examination made at one of these hospitals, in which one 15 by 12 in. and one 10 by 12 in. film was taken, a gastric ulcer was entirely missed, and the films were almost unintelligible; five guineas was charged. Later the patient came to me and by means of eight 15 by 12 in. films (fee seven guineas) a gastric ulcer was displayed.

What is not realized is that much of this hospital barium meal work is seen only once, if at all, by the radiologist, and the rest of the examination is carried out by a lay radiographer—in contrast with the work of a private radiologist, who screens the patient at least six times, and usually has some knowledge of the physiology and pathology of the intestinal tract.

The private radiologist for practically the same fee has to provide comfortable waiting rooms, whereas at a hospital the patient has invariably to sit for hours on a hard bench and is often treated in a supercilious manner by lay assistants and attendants. Also the patients are seen by appointment, usually at their own convenience, by the private radiologist, whereas hours of waiting and several days' delay are often entailed in a hospital. If an error is made responsibility is definitely fixed in the case of the private radiologist, whereas in hospital work there is abundant opportunity of shifting the responsibility for bad work and error. Further, the private radiologist invariably rings up the practitioner and gives him the result immediately after examination and sends the films within twenty-four hours, whereas, to my knowledge, practitioners have waited a week for a hospital report, and then had only a brief written report and no opportunity of seeing the actual films. The private radiologist has, in his own interest, to watch the interests of the practitioner sending the case to him, but it is not unknown in hospitals for some lay assistant to make derogatory remarks regarding the practitioner's provisional diagnosis.

Whether a charitable hospital is justified in charging the above fees is a matter for considerable doubt. Very often the visiting radiologist receives one-half of the fee, and in the Memorandum two-thirds of the fee is stipulated. From the hospital side this one-third of the fee hardly covers the cost of the films; and overhead charges, such as assistants' salaries, capital cost, and upkeep and depreciation of tubes and plant are being borne by the charitable side of the hospital. These, however, are being used for the advantage of the visiting radiologist, who often comes from a considerable distance and is entering into unfair competition with a local radiologist, who has to pay rent, rates, light charges, etc., serious items with which the hospital radiologist has no concern.

As a hospital radiologist of some years' standing I have seen many paying patients at hospitals, but the fees in their entirety have gone to the hospital, as my own view is that the radiologist has no right to use hospital apparatus and accommodation for his private gain, particularly while a hospital is appealing for charitable subscriptions. The radiologist is fully entitled to a salary for often onerous duties. The willingness of many radiologists to accept a hospital post to which no salary is attached, with the intention of starting what is really a local private practice with the hospital's facilities, explains why radiological posts advertised tend more and more to offer no salary or honorarium. Such an exploitation of hospital facilities has no moral warrant, and if generally known would undoubtedly lead to a loss of charitable subscriptions.

In contrast, we have the hospital which offers the radiologist a small honorarium and then exploits his services to its financial advantage. For several years I examined cases for the London County Council and various borough councils. As these patients were admitted with out-patient notes bearing the hospital's name only, I was not, until too late, aware that my services, given for charitable patients, were actually being exploited for the benefit of municipal bodies well able to pay for them. A computation showed that at least £500 should have been paid by the borough councils under the British Medical Association resolution of 1921, or £125 per annum, additional to an honorarium of fifty guineas per year for services to the charitable side of the hospital. Not only was the hospital exploiting these practically honorary services, but, if the hospital had not used its x-ray department supported by voluntary subscriptions for this purpose, the various borough councils would each have found it necessary to install a plant and pay radiologists the recognized fee of £150 per year per attendance per week.—I am, etc.,

May 9th. A HOSPITAL AND PRIVATE RADIOLOGIST.

MATERNAL MORTALITY.

SIR,—The Minister of Health has stated that medical practitioners are being asked to supply information from their experience which may suggest means for the reduction of the high maternal mortality. In spite of better trained midwives and medical men, a more general application of the principles of antisepsis and asepsis, and less meddlesome midwifery, the percentage of mortality remains practically constant. Perhaps my own experience as a rural practitioner since 1898 may throw light on this apparent anomaly.

During my first twelve years of country practice in North Derbyshire I was only rarely able to obtain the services of a trained nurse or a certified midwife; in general, the nursing was done by a neighbour, and, in spite of the pressure I brought to bear, the standard of cleanliness was often not very high. But I do not remember losing a single case from sepsis. It was a healthy district; the women led active, healthy lives, grew their own vegetables, and drank pure water from the hills. The majority were able to help themselves in labour.

I find to-day that women have become less able to face labour and to help themselves; they are exhausted early in labour, cry out for chloroform long before they should have it, and, above all, they are more liable to sepsis. Moreover, I know cases where the patient delivered herself before the nurse or doctor had time to do anything, where everything was perfectly clean, and yet sepsis developed. My experience suggests that in a very high percentage of cases the patient, even before labour, is suffering from sepsis, which is ready to flare up when her vitality, already low, is still further lowered by the exhaustion of labour. Many women who develop puerperal sepsis are suffering from pyorrhœa or septic tonsils; the majority suffer from chronic constipation with auto-intoxication. My view is that the ultimate cause is bad feeding and bad hygiene. Notwithstanding all that we have learned about the importance of vitamins in the diet, many people consume vitamin-deficient foodstuffs in large quantities—white bread, pastry, steamed puddings—and when they have loaded their stomachs with these they have no appetite left for natural foods such as vegetables, fruits, rice, and oatmeal, all of which are rich in vitamins. Inevitably with such a dietary they suffer from intestinal stasis and are exposed to its consequences. I believe that good feeding and the prevention of constipation will go far to prevent maternal mortality, and that it is the duty of the medical attendant of the pregnant woman to supply her with a suitable diet sheet and instructions about personal hygiene which will serve to promote her own welfare and that of the unborn child.—I am, etc.,

J. A. BENSON, L.R.C.P. and S.Ed.

Green Hammerton, York, May 3rd.

HEROIN AFTER ABDOMINAL OPERATIONS.

SIR,—With reference to Mr. Woolf's article on the use of heroin after abdominal operations, which was published on March 16th (p. 499), it may be of interest to record a case I had recently under my care.

A man, aged 35, was suffering from great pain from lumbago of obscure origin, so that he lay groaning in his bed. He begged me not to give him morphine, as it had nearly killed him before, so I gave him one-sixth of a grain of heroin hydrochloride. About half an hour later I was called back by a very anxious messenger, who told me the man was dying. I found him cyanosed and apparently not breathing at all, but the heart was still beating, so I waited, and after a few minutes he gave a deep snoring breath, much to my relief. I performed artificial respiration, apparently without avail, and in the meantime another doctor was called in, without my knowledge. I reassured the people as much as possible, and told them to hold the jaw well up to avoid the awful snore when at last the breath should come, as it was sure to do, I said. I then left the case in the hands of my colleague, while I gave an injection of strychnine hydrochloride 1/12 grain—a big dose, for I felt that a desperate case required desperate measures. After a few minutes cramps followed, and I was afraid I had poisoned him with strychnine, but fortunately in about two hours' time the breathing improved and he went off into a quiet sleep.

While my colleague was looking after him I went home to hunt up the known toxicity of heroin, and I found that this

was very much less than that of morphine; moreover, I found that as much as nine grains had been taken accidentally, with recovery. So I felt greatly relieved, and went back and confidently assured his weeping wife that her husband would recover. Perhaps lobeline might have been useful as a respiratory stimulant. The condition was undoubtedly alarming, as he became quite black during the lapse of fully three minutes, when another deep breath was taken. Perhaps it will be safer in future never to begin with more than the maximal pharmacopoeial dose of one-eighth of a grain.

I should mention that just at that time I happened to be treating a young man in the last stage of consumption who was suffering from very severe pains in the legs, for which he had been æ-rayed and examined by the best nerve specialists in the land without avail. Nobody could find out the cause of these pains, but as they were quite unbearable I had been obliged to give morphine up to 2 grains, which made him too dry and sick, so that I had been compelled to give heroin, in 2-grain doses, hypodermically. I once gave it intravenously, but as the effect was somewhat alarming I afterwards always administered it hypodermically, often twice a day. After a few minutes he was quite normal and cheerful, taking a lively interest in current events, whereas before he had been crying piteously, unable to swallow any food or even to speak.

It would be interesting to know if heroin is really as dangerous as it looks, judging by its profoundly depressing influence on the respiration. What is the minimum lethal dose?

I am strongly under the impression that the very violent measures taken by Mr. Woolf to restore normal respiration, causing dislocation of the arm, were superfluous. The respiratory centre wanted a strong stimulus; filling the lungs with air by artificial respiration would diminish rather than increase that stimulus, or so it would seem to me. In my case, when I gave up interfering with the respiration (reassured by the fact that even nine grains had failed to kill!) the breathing soon began to improve, though how far this may have been caused by the strychnine is difficult to say. After the respiratory centre has already been depressed by a general anaesthetic, it is probably wise not to give more than 1/12 grain, especially to elderly women, as the cases quoted. As a rule 1/12 grain is not enough to relieve pain, but it depends very much on the body weight and the severity of the pain.—I am, etc.,

S. J. D. ESSER.

Rustenburg, Transvaal, April 23rd.

DEFECTIVE HYPODERMIC NEEDLES.

SIR,—In the recent annual report of the London and Counties Medical Protection Society, Limited, attention was called to the extraordinary number of cases referred to the society in which litigation had been threatened owing to the breaking of hypodermic needles. I suggest, Sir, that many of these cases are due not so much to carelessness on the part of the doctor as to the presence on the market of a certain number of badly made needles. Personally I have so little confidence in the reliability of steel needles that I have almost entirely abandoned them, and for the last two years have used platinum-iridium instruments. No doubt manufacturers, as a rule, endeavour to turn out good quality material, but I doubt if some of them quite realize the trouble and anxiety which may be caused by, say, 1 per cent. of bad hypodermic needles.—I am, etc.,

T. W. PRESTON, M.D.

London, W.1, May 21st.

The Services.

DEATHS IN THE SERVICES.

Major-General William Wallace Kenny, C.B., Army Medical Staff (ret.), died at Clifton, York, on May 11th, aged 74. He was born at Killeshandra, co. Cavan, on July 14th, 1854, the son of the late Randal Young Kenny, and was educated at Trinity College, Dublin, where he graduated as B.A. and M.B. in 1876, after taking the L.R.C.S.I. in 1875. Subsequently he became F.R.C.S.I. in 1889. Entering the R.A.M.C. as surgeon on August 5th, 1877, he attained the rank of colonel on April 1st, 1904, and surgeon general on June 8th, 1908, and retired on December 4th, 1914, but was immediately re-employed from the same date, and served to the end of the war in 1918. He took part in the Afghan war in 1879-80, serving on the Khaiber line (medal); in the Sudan campaign of 1885, at Suakin, and in the actions at Hashin, Tofrek, and Tamai (medal with two clasps, and Khedive's bronze star); in South Africa in 1900, as P.M.O. of the 10th Division, in the operations in Cape Colony, including the action at Ruidaur (Queen's medal with two clasps); and in the recent war of 1914-18 (medal, star, and victory medal). In 1903-4 he was superintending medical officer in Jamaica, chairman of the Board of Health, and member of the Legislative Council. As surgeon general he served in the York Command. He was appointed honorary surgeon to the King in 1910, received the C.B. in 1917, and was also a Knight of Grace of the Order of St. John of Jerusalem. In 1882 he married Catherine Jane, daughter of E. B. Steedman, Esq., of High Ercall Hall, Wellington, Salop. She died in 1920; he leaves two daughters.

Surgeon Commander James Walter Octavius Underhill, R.N. (ret.), died in the London Hospital on April 29th. He was educated at Edinburgh, where he graduated as M.B. and C.M. in 1884, and entered the navy as surgeon on August 20th, 1885, becoming staff surgeon after twelve years' service, fleet surgeon in 1902, and retiring in 1907. The title of his rank was changed in October, 1918. He had served in H.M.S. *Boadicea*, from 1888, when she was flagship of Rear-Admiral the Hon. Sir Edmund Fremantle in the East Indies. Later he served in the battleships H.M.S. *Duncan* in the Mediterranean, and H.M.S. *Hindustan* in the Atlantic fleet. He rejoined for service when the war began, in August, 1914, and was appointed principal medical officer of the *Excellent*, gunnery school, Portsmouth, and served there till January, 1916.

Major Stephen Harry Creagh, R.A.M.C. (ret.), died at Haughley House, Suffolk, on May 6th, aged 74. He was born on August 14th, 1854, and entered the army as surgeon on July 30th, 1881, became major after twelve years' service, and retired with a gratuity on August 23rd, 1899.

Lieut.-Colonel George Edward Weston, R.A.M.C. (ret.), died at Exmouth on May 2nd, aged 72. He was born at Maiden Newton, Dorset, on July 5th, 1856, was educated at St. George's, and took the M.R.C.S., L.S.A., and L.R.C.P.Ed. in 1880. Entering the R.A.M.C. as surgeon on July 30th, 1881, he became lieutenant-colonel after twenty years' service, and retired on July 17th, 1909. He served in the Bechuanaland campaign of 1884-85; in the campaign of 1887 on the Egyptian frontier (medal and Khedive's bronze star); and in the South African war in 1902, taking part in operations in Cape Colony and the Orange River Colony, receiving the Queen's medal with three clasps. He was also re-employed during the recent war, from June 17th, 1915.

Universities and Colleges.

UNIVERSITY OF OXFORD.

IN Convocation on May 21st a decree was passed recording the gratitude of the University to Mr. Gilbert Varley for his offer to place at its disposal the sum of £6,000, subject to a life annuity, for the furtherance of medical research, in accordance with the wishes of his brother, the late Richard Stanley Varley.

UNIVERSITY OF LONDON.

Lord Dawson of Penn, Mr. H. L. Eason, and Sir Cuthbert Wallace have been elected the representatives of the Faculty of Medicine on the newly constituted Senate of the University.

The Dunn Exhibitions in Anatomy and Physiology for 1929 have been awarded respectively to Mr. W. Mushin of the London Hospital Medical College, and Mr. B. Gilbert of St. Thomas's Hospital Medical School.

Dr. Winifred Cullis, C.B.E., Professor of Physiology in the University, has been elected Deputy Chairman of Convocation.

UNIVERSITY COLLEGE.

The examination for the Bucknill Scholarship (160 guineas) and for two Exhibitions, value 55 guineas each, will begin on June 25th. The subjects of the examination are chemistry, physics, botany, and zoology. The scholarship and the two exhibitions are tenable at University College, London. Application for entry forms should be made to the Secretary of University College, Gower Street, W.C.1, not later than June 1st.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

THE following 30 successful candidates (out of 85 entered), having passed the requisite examinations, were admitted Fellows on May 15th:

H. Abernethy, R. E. Austin, H. S. Bilcliff, B. B. Blomfield, D. C. Bowie, R. P. Chari, W. N. Chisholm, J. G. A. Davel, G. A. Davies, H. G. Estcourt, J. L. Farquharson, D. J. D. Henderson, R. A. Highmoor, A. E. King, M. G. Kini, E. R. Lange, C. G. Lewis, A. J. G. Mackay, Y. S. Moholkar, S. Newson, W. J. Pannell, L. M. Park, L. V. Pearson, L. S. Rogers, M. G. Saincher, C. G. Schurr, R. N. Sewal, G. G. Talbot, J. R. Wheeler, G. Wood.

The Bathgate Memorial Prize, consisting of bronze medal and set of books, after a competitive examination in materia medica, has been awarded to Mr. Wai Ming Tso.

Obituary.

ARTHUR H. CHEATLE, C.B.E., F.R.C.S.,

Late Aural Surgeon, King's College Hospital, and Lecturer on Aural Surgery, King's College Hospital Medical School.

WE had to announce with deep regret last week the death, at the age of 62, of Mr. Arthur H. Cheatle, which took place in London on May 11th.

Arthur Henry Cheatle, after receiving his early education at Merchant Taylors' School, proceeded to his medical studies first at King's College Hospital, London, and, later, in Vienna. In 1888, having qualified as M.R.C.S., L.R.C.P., he held a number of appointments at King's College Hospital, serving for a time as house-surgeon to Lord Lister, and as assistant house-accoucheur, and later as house-accoucheur to the hospital. In 1892 he proceeded to the Fellowship of the Royal College of Surgeons of England, and after a period devoted to the study of aural surgery in Vienna he returned to England, and was appointed assistant aural surgeon to King's College Hospital. On the retirement of Dr. Pritchard he became aural surgeon. At the Ninth International Otological Congress he was awarded the Adam Politzer prize, and he held, among other positions, the Hunterian professorship of the Royal College of Surgeons, the presidency of the Section of Otology at the International Congress of Medicine in 1913, of the Section of Laryngology and Otology of the British Medical Association when it met at Bath in 1925, and of the Otological Section of the Royal Society of Medicine. For a time he was examiner in laryngology and otology to the Royal Colleges of Physicians and Surgeons. During the war he served as lieutenant-colonel in the medical branch of the Royal Air Force, acting as honorary consultant to the military hospitals of the London and Eastern Command and aural surgeon to the King Edward VII and King George Hospitals. He was for many years a member of the British Medical Association, and held, prior to his presidency of the Section of Laryngology, the office of secretary of that Section when the Association held its last Annual Meeting in Manchester in 1902, and of vice-president of the same Section at the Annual Meeting held in Liverpool in 1912.

ARTHUR H. CHEATLE, F.R.C.S.
(Photograph by Malcolm Arbuthnot, London.)

Perhaps Arthur Cheatle's greatest contribution to aural surgery was in his preparation of specimens—over 700 in number—to illustrate the variations in the anatomy of the mastoid region, and the influence of the anatomical type on the clinical features and progress of middle-ear infection. This collection he presented, in 1911, with a descriptive catalogue written by himself, to the Museum of the Royal College of Surgeons of England, as a supplement to the famous Toynbee collection, continuing, in later years, to add many other preparations and to keep the catalogue up to date. Cheatle's specimens illustrate the age and sex variations in the form and structure of the temporal bone; they provide the basis of anatomical fact on which rest the present-day operations on the mastoid region. He proved that the dense mastoid was not, as was commonly held, the product of chronic inflammation, but a normal anatomical type of bone which is causative indirectly of chronic suppurative middle-ear disease.

From his publications one may single out for mention *Sight and Hearing in Childhood* (with the late R. Brudenell Carter); *A Report on the Examination of the Ears and Throats of 1000 School Children*; *Gun Deafness and its Prevention*; Hunterian Lectures on "The surgical anatomy of the temporal bone"; the "Petro-squamosal sinus, its anatomy and pathological importance," published in the *Transactions* of the Sixth International Congress of Otology, and the "Symmetry of the temporal bone," in the *Transactions* of the Ninth International Congress.

Arthur Cheatle was a man of shy and retiring disposition, slow to make friends, but deeply admired by those who had the privilege of his friendship. So scrupulously did he avoid publicity that others received credit for discoveries in aural surgery which he himself had made. As a worker he was patient, careful, and indefatigable, making all the preparations in his collection with his own hand. His death is a great loss to aural surgery. On behalf of many colleagues in the medical profession we offer sympathy to his brother, Sir G. Lenthal Cheatle, senior surgeon to King's College Hospital.

DR. PERCY FREDERIC BARTON, who died on May 11th, aged 60, received his medical education at Cambridge and St. Thomas's Hospital. He obtained the diplomas M.R.C.S., L.R.C.P., in 1896, and graduated M.B., B.Ch. in 1899. After conducting a large general practice for many years he devoted himself with increasing interest to psychotherapy, and was appointed physician to the Tavistock Clinic for Functional Diseases. He was a member of the British Medical Association and of the British Psychological Society. Dr. H. Crichton Miller writes: Dr. Barton joined the staff of the Tavistock Clinic in October, 1921, one year after its foundation, bringing to the treatment of functional nervous disorder the ripe experience of a mature and successful general practitioner. He had been interested in psychotherapy for many years, and finally he decided to give up the work of a lifetime in favour of specialization. He underwent analytical treatment, and threw himself with zest into the work of the clinic. For about six years he was one of the most industrious and helpful members of the staff, but, latterly, the demands of private practice precluded him from regular attendance at the clinic, and when the category of honorary physicians was instituted, his name was one of the first four to be inscribed. I should like to record my own impressions of a dear personal friend and a very valued colleague. He was an extraordinarily social man, who made friends everywhere, and it was the breadth of his human interest and sympathy that underlay all his psychotherapy. His convincing sincerity, his simplicity, and his magnanimity contributed to the attraction of the man and the success of the physician. He was no "brittle intellectual," but his mentality ran rather to a certain common-sense downrightness that was impatient of needless elaboration and subtlety. What is perhaps of most interest to us as psychotherapists is the elasticity of a mind that after middle life could assimilate, as his did, views in many ways so divergent from those of the rigid school in which he had been brought up. I cannot help feeling that he was able to achieve this by reason of that sense of humour which never deserted him, and which helped him to maintain a wholesome self-criticism at an age when most of us have settled down into

complacent self-acceptance. Finally, Dr. Barton was a man devoid of any streak of cynicism. Many a time he has described to me with peals of boyish laughter some absurd case of human fatuity, and yet one was conscious that through it all the man was "vigorous with spiritual purpose."

The death took place suddenly, on May 3rd, of Dr. D. J. PENNEY, who had an extensive practice in Rothesay. Born in 1866, he graduated M.B., C.M. at Glasgow University in 1887. After a period spent as resident surgeon in the Western Infirmary of Glasgow, he settled in Rothesay, and became medical officer of health for the Bute district. He was also Admiralty surgeon and agent, and took a great interest in the local territorial artillery, and was mobilized as a major in the R.A.M.C. during the period of the war. He held the Territorial Decoration for length of service. Dr. Penney was an active member of the British Medical Association and a Fellow of the Glasgow Obstetrical and Gynaecological Society.

The death occurred, on May 12th, of Dr. JOHN STOTHART BELL, at his residence, The Green, Lockerbie, Dumfriesshire. Dr. Bell was 70 years of age, and graduated M.B., C.M.Ed. in 1887. In the following year he settled in his native county at Lockerbie. In addition to carrying on an extensive practice, he was parochial medical officer for Applegarth, and held other public appointments. Keenly interested in education, he was for many years a member of the old Dryfesdale School Board. He is survived by one son, Dr. Douglas Bell, who succeeds him in the practice, and two daughters.

We regret to record the death of Dr. ROBERT INCH, which took place at his residence, *Stobmills House*, Gorebridge, Midlothian, on May 12th. Dr. Inch, who was 69 years of age, graduated M.B., C.M. at the University of Edinburgh in 1883. For more than forty-five years he had been in practice at Gorebridge. His practice covered a wide area, and entailed, in the earlier years particularly, a great deal of travelling and hardship. Dr. Inch was medical officer of the Newton Loan Hospital for Infectious Diseases, parochial medical officer for the Cockpen and Temple districts, and chairman of the Panel Committee for the county of Midlothian. A keen volunteer, he was medical officer and lieutenant in the 1/1 Midlothian Volunteers. He took a great interest in educational affairs. For many years he was a member of the old School Board, and for a period he was chairman. When the School Board ceased to function he was elected the first chairman of the Midlothian Education Authority, and on the occasion of his retirement recently was entertained by his colleagues. He was also a justice of the peace for Midlothian. Dr. Inch is survived by his wife, a daughter, and a son, Dr. T. Douglas Inch, *M.C.*, who has assisted his father since the war. A younger son was killed in the war. There was a large attendance of the general public at the funeral service in Stobhill Parish Church and at the graveside in Cockpen churchyard. Many of the public bodies with which Dr. Inch had been associated were represented.

The following well-known foreign medical men have recently died: Dr. BALZER, a prominent Paris dermatologist, honorary physician of the Hôpital St. Louis, and member of the Académie de Médecine; Dr. VAN DIEST, principal medical officer of the Belgian Congo; Dr. AUGUST PÜTTER, professor of physiology and director of the Institute of Physiology at Heidelberg, aged 50; Professor ROBERT ASCH, a leading gynaecologist and obstetrician of Breslau, aged 70; Professor JACQUES LOUIS REVERDIN of Geneva, aged 86; Professor S. T. SÖRENSEN, formerly director of the Blegdams Hospital, Copenhagen, and a leading authority on acute infectious diseases; Dr. JOSÉ MARIA LOMBANA BARRENECHE, professor of clinical medicine at *Bogota*, and Dr. BILLARD, professor of physiology at the *Clermont-Ferrand* medical school.

Medical News.

THE next meeting of the Society for the Study of Inebriety will be held in the rooms of the Medical Society of London, 11, Chandos Street, Cavendish Square, W., on Tuesday, July 9th, at 4 p.m., when Mr. W. McAdam Eccles will deliver his presidential address on "Some gaps in the study of inebriety," and Sir William Willcox will open a discussion on "The toxic effects of methylated spirits and impure forms of alcohol."

THE St. Cyres Lecture for 1929 will be delivered at the National Hospital for Diseases of the Heart, Westmoreland Street, W.1, on Thursday, June 6th, at 5 p.m., by Dr. R. O. Moon; the subject is "Some observations on diseases of the myocardium." Members of the medical profession are cordially invited.

THE Linacre Lecture, delivered in Cambridge on May 6th by Dr. Peyton Rous of the Rockefeller Institute for Medical Research, is being published by the Cambridge University Press. The title is *The Modern Dance of Death*.

LIEUT.-COLONEL G. S. PARKINSON, D.S.O., R.A.M.C. (ret.), has been appointed assistant director of hygiene (part-time) at the London School of Hygiene and Tropical Medicine. During the late war Colonel Parkinson was deputy assistant director of hygiene with the 1st Army, and later assistant director of medical services. After the armistice he was D.A.D.H. at Gibraltar for five years, and was then appointed assistant professor of hygiene at the Royal Army Medical College, Millbank.

THE second annual meeting of the reorganized Continental Anglo-American Medical Society was held on April 30th in the salons of the new casino at Nice, and was an extremely enjoyable and successful gathering. The honorary secretary of the society is Dr. B. Sherwood-Dunn, 54 Bd. Victor-Hugo, Nice, A/M., France. It is proposed to hold the next annual meeting in Florence.

LISTS of medical practitioners serving as members of local authorities or their subsidiary public bodies in Great Britain were published in our issues of December 8th (p. 1057) and December 29th, 1928 (p. 1190), and February 16th (p. 314), April 13th (p. 702), April 27th (p. 795), and May 11th, 1929 (p. 889). We have since been notified that Dr. G. M. Blnett has for the past three years been the only medical member of the Guildford Board of Guardians, that Mr. H. H. Raw is a member of the Whitby Urban District Council, and that Dr. W. B. Cathcart is [illegible] Urban District Council and [illegible] Committee.

THE third report of the Gas Cylinders Research Committee, which relates to alloy steel light cylinders, has been issued by the Department of Scientific and Industrial Research, 16, Old Queen Street, Westminster, S.W.1, and may be obtained from H.M. Stationery Office at the price of 2s. 6d. The first of these reports, which dealt with cylinders for use in commerce for the transport of "permanent" gases, is out of print, but a summary of recommendations containing revisions from this report is now in the press.

FOLLOWING the congress entitled *Journées Médicales de la Faculté de Paris*, an excursion has been arranged to the health resorts in the Cevennes and Pyrenees, from June 14th to 25th. Places to be visited include: La Malou, the Gorges-du-Tarn, Carcassonne, Luchon, Cauterets, and Lourdes. Relatives of medical practitioners are invited and also medical students. Further information as regards the cost and details of the tour may be obtained from the office of the Voyages Médicaux Pyrénéens, La Malou, Hérault, France.

THE sixth international antitobacco congress was held in Paris on April 2nd, when the following papers among others were read: the pathogenic action of tobacco, by Dr. G. Petit; the offensive alliance between alcohol and tobacco, by Dr. Legrain; and the argument of personal liberty in the anti- [illegible] by M. Stricker, formerly Minister of Public [illegible].

IN connexion with the congress known as the Journées Médicales" of Evian, which will be held on September 14th and 15th, a tour has been arranged through various climatic resorts in the Alps from September 3rd to 14th. The places visited include: Vals, Grenoble, Grande-Chartreuse, Aix-les-Bains, and Chamonix. The cost of the tour is 950 francs; it is open to medical practitioners and to medical students in their final year. Further information may be obtained from Madame Juppé-Blaise, Federation of the Health Resorts of France, 1, Gordon Square, W.C.1.

A COURSE on oto-rhino-laryngology will be held at Strasbourg from July 1st to 14th under the direction of Professor Canuyt, assisted by Drs. Barre, Bellocq, Borrel, Pautrier, Grusett,

Vaucher, and Joublot. The programme will include clinical instruction, demonstration of apparatus, and operations. The fee is 400 francs.

THE late Sir Alexander Ogston has left, in addition to considerable real estate, personal property in Great Britain valued for probate at £40,278.

THE May issue of *The Mission Hospital*, which is published by the Church Missionary Society, contains an interesting account by Dr. G. E. Dodson of the progress made in Persia as regards medical treatment and sanitation during the last twenty-five years. In the same issue there is a memorial note about Dr. E. F. Molony, who went out to Persia as a missionary in 1926 and died in Kerman last February.

RECENT celebrations have included that of the seventy-fifth anniversary of the Spanish journal *El Siglo Medico*, and of the second centenary of the birth of Lazzaro Spallanzani, at Reggio Emilia. In June the University of Toulouse will celebrate its seventh centenary, and the Academy of Medicine of Rio de Janeiro the centenary of its foundation in July.

WE have received the first issue of *Fortschritte der Neurologie, Psychiatrie und ihrer Grenzgebiete*, a monthly journal published at Berlin under the editorship of Professors A. Bostroem and J. Lange. Its object is to provide concise surveys of recent progress in neurology, psychiatry, and allied subjects. The present issue contains articles by Erich Guttmann of Munich, on "Non-systematic diseases of the spinal cord, its roots and meninges"; by Arthur Kronfeld of Berlin, on "Advances in psychotherapy"; and by Gottfried Ewald of Erlangen, on "The endogenous psychoses."

THE issue of the *Wiener klinische Wochenschrift* for May 9th has been dedicated to Professor Julius Hochenegg, director of the second university surgical clinic of Vienna University, on the occasion of his having occupied this position for twenty-five years.

THE Paris Lyons and Mediterranean Railway announces that the through Pullman express between Boulogne and Vichy will commence running on June 15th in connexion with the 9 a.m. service from Victoria.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9861, 9862, 9863,* and *9864* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:
EDITOR of the *British Medical Journal, Aitiology Westcent, London.*
FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*
MEDICAL SECRETARY, *Mediocera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

FLUSHINGS.

"EREBUS" asks for any treatment likely to improve a lady, aged 56, who, after hysterectomy and appendicectomy, gets sudden flushings of face and other parts of the body, which make her feel unable to do anything and depress her. The flushings occur at nights and keep her awake; she is anaemic and nervous; ordinary treatment has not availed.

DISSEMINATED SCLEROSIS FOLLOWING PREGNANCY.

DR. E. COLLIER (Felling-on-Tyne) writes: I have at present under my care a case of disseminated sclerosis which has occurred as a sequel to pregnancy. The patient, a young married woman, aged 25, on getting up on the tenth day after her third normal confinement and puerperium, discovered that she was very weak on her legs, and giddy. The symptoms have progressed until now, one month after the confinement, she presents most of the features of disseminated sclerosis. I shall be glad to know if any of your readers have met with similar cases of disseminated sclerosis coming on after pregnancy. I may add that I have ruled out the question of it being a hysterical condition.

SEQUELS OF INJECTIONS OF VARICOSE VEINS.

"M.B., C.M." writes to say that he has had varicose veins in both legs for many years. Lately the varices were successfully occluded by the quinine-urethane solution, but the "tired" feeling still remains after a short walk, and the local oedema, which was always present before, still persists, so that he has to wear elastic stockings, as of yore, to give the desired support. There is no pitting on pressure, and the swelling is quite local. He now wonders if the deep veins are varicose, and is desirous to know of anything that would expedite a cure, if any. He adds that sixteen injections of the solution were made in five days without any untoward results.

AFTER-EFFECTS OF "TWILIGHT SLEEP."

DR. E. CURNOW PLUMMER (London, N.W.) writes: With reference to Dr. Frank E. Kingston's inquiry in the *Journal* of May 18th (p. 938), the amnesia of "twilight sleep" is not a "deliberate forgetting," but a mental state induced by the drugs employed. I have given "twilight sleep" to several hundred patients, some of them twice and three times, and have kept in touch with many of them. Having also dealt with many other patients with various psychoneuroses, I have been on the alert, but in no single instance have I seen any psychoneurosis that could be attributed to "twilight sleep." On the contrary, prospective mothers who had a dread of childbirth almost amounting to an anxiety state have, after a successful "twilight sleep," completely lost their fears and been able to contemplate later pregnancies quite calmly, so being freed from a possible cause of psychoneurosis.

AXILLARY HYPERIDROSIS.

DR. J. J. MARLBOROUGH (Gort, co. Galway) writes in answer to "D. G.'s" inquiry of April 27th (p. 795): I have found a 25 to 30 per cent. solution of aluminium chloride in distilled water perfectly satisfactory in a number of cases of localized excessive sweating. The application is allowed to dry on, and is renewed every second or third day. Three applications at these intervals may be made, and then the parts should be left for a week, or until recurrence shows itself. The lotion should be allowed to dry completely before clothing is resumed. Some slight momentary irritation may be caused by the application.

"X. Y." writes: I suggest the use of liquor formaldehyde saponatus (*B.P.*). This is, I believe, an excellent skin antiseptic in cases of dysidrosis, and has a decided drying effect upon the sweat glands. A few drops rubbed over and allowed to dry on the skin are quite effective.

PAINFUL HEEL.

"G. F. P." writes: I suggest that the condition of "painful heel" complained of by "Giza's" patient (May 11th, p. 890) may be due to constriction of the circulation of the foot resulting from undue flexion of the ankle while operating the accelerator pedal in driving a car. I have recently had puzzling symptoms of the same kind, which were relieved by raising the heel of the right foot by means of a wooden block screwed to the floor boards. The wearing of boots, especially if rather tightly laced, is probably a predisposing cause.

DR. W. JOHNSON SMYTH (Bournemouth) writes: The painful heel condition referred to by "Giza" is probably a peripheral neuritis affecting the calcaneal branches of the posterior tibial and external saphenous nerves. As bone disease is excluded the case is a hopeful one. I find that these cases get well after a few days' treatment by diathermy. The treatment is given twice daily; the heel being wrapped up in chamois leather between the applications. Rest in bed or on a couch is essential. Alcohol to be excluded; 1/4 grain of calomel to be given every six hours before meals.

INCOME TAX.

Depreciation of Car.

"A. E. B." inquires whether he can claim depreciation in respect of a car bought new, not by way of replacement, in 1926; his auditor says "such a change can be made only if and when it is replaced by another car."

*** Yes, he can, and in our opinion should, claim depreciation. On the 15 per cent. basis the amount to be claimed for 1929-30 would be calculated as follows:

Value at December 31st, 1927	£300−£45=£255
,, December 31st, 1928	£255−£38=£217
Depreciation for 1929-30—£217 at 15 per cent.	=£32

It will be seen that "A. E. B." has lost, temporarily, the allowance for 1927-28 and 1928-29, but this will be allowed for when the car is renewed if an "obsolescence" claim is then made.

Car Transactions.

"W. L. T." bought a car in 1923 for £250 and sold it in 1928 for £5, when he bought a car of a different make for £192. The inspector of taxes will allow the cost of renewal—that is, £192−£5=£187, but not depreciation on the new car.

*** We advise our correspondent to accept that view, which has judicial support, but to claim depreciation allowance for the

year 1930–31, the gross liability for which will not be affected by the renewal allowance. Assuming the appropriate rate to be 20 per cent., he will be losing for the time £38, but if he remembers to claim *obsolescence allowance* when he replaces his present car the temporary loss of allowance will then be automatically put right.

"G. B. S." bought a second-hand car in 1926 for £115, and commenced practice in January, 1927. He has been allowed the aggregate amount of £30 for depreciation, and has now sold the car for £30 and bought a new one for £130. What should he claim?

*** (1) Obsolescence allowance £115–£30–£30=£55 and (2) depreciation on the new car £130 at 15 per cent.=£20. Strictly, the former amount—that is, £55—should be reduced by the proportion applicable to the use in 1928, as compared with the amount of use after professional work was commenced, but apparently this would be almost, if not quite, negligible.

Emoluments of Assistant.

"J. H. R." was employed as an assistant. For the first four months he received a cash payment as salary, and the cost of his board and lodging was paid by his principal. Subsequently, as a matter of convenience, the principal "suggested that he should include the cost of board in the monthly cheque paid" to "J. H. R." and that the latter should pay the landlady on the former's behalf. "J. H. R." has been assessed to tax on the total cash payments. What are his prospects of a successful appeal?

*** It is, of course, clear that under the original arrangement "J. H. R." was not liable for the value of the advantages received by way of lodging. The question is whether the change brought him into the position of receiving cash, subject to a compulsory application thereof to the cost of his board, etc. The distinction is, in any case, a fine one, but it will assist our correspondent in his argument if he can show that the cash payments to him fluctuated precisely with the amounts payable to his landlady—that is, that his principal received the advantage of any allowances for absences, etc., and bore the cost of fluctuating extras. If that was the case the argument that the payments by the principal were made to the landlady, "J. H. R." being merely the channel by which they reached her, is strengthened. If this cannot be proved, we fear that the decision would go against "J. H. R.," on the broad grounds that he lacks equity—having had the benefit accruing from the payments—and that, so far as the legal position is concerned, the cash actually passed into his possession.

Occasional Residence in this Country.

"F. F. M." refers to an answer given to "Cerons" in our issue of May 11th, and asks how is income from investments "charged by way of security in favour of the annuity," and also whether "a married person living for any length of time in England (in his wife's flat) is liable to income tax on any income he receives, whether it is paid in England or France."

*** The law dealing with liability arising out of occasional residence in this country is more than ordinarily complicated, and the decision to be arrived at depends usually on a general view of all the circumstances of a particular case, and we cannot undertake, therefore, to give an adequate reply in these columns. Briefly, however, income may be charged in the manner suggested by making it legally payable to trustees appointed to see that the annuity is duly paid, or by giving a lien on the securities themselves. In the circumstances mentioned the husband would become a British resident as soon as he came to the country, but might be regardable as an "occasional" resident if his return to the United Kingdom were not habitual. If he is an occasional resident only, he would not be liable on income accruing abroad from stocks, shares, or rents, but not coming to the country; if he is a resident, and not an occasional resident, he is liable, whether such income is received here or not.

LETTERS, NOTES, ETC.

The Use of the Tonsils.

Dr. F. G. Gardner (Oxford) writes: Several letters have appeared lately under the above heading; without expressing an opinion, may I be allowed to state a relevant fact? In Abyssinia it has been the custom from time out of mind, I believe, to remove the tonsils of all children in infancy. That the custom is without bad after-effects may be inferred from the fact that this people is always described as a "warlike, big, and well-grown race," and England, in sending out diplomatic missions there, has always paid deference to these qualities by choosing men who were also "big and well grown," in order to produce a good moral effect. [illegible] claim that as a nation they have never been [illegible] believe they came very near to subjection in [illegible]. Some time ago I attended a meeting at [illegible] ead by an experienced surgeon on removal of the tonsils, raising the question of the remote effects of total removal on the general health. In the discussion I described the Abyssinian custom as a gigantic "control" experiment spread over a whole people during a very long period; this appeared to be news to the meeting. I stated that I believed the tonsils were removed by means of the index finger-nail. Since then I have been able to obtain a little further information through the kindness of an English resident. I gather that removal is effected by means of a horsehair noose. If this gives way it is left in situ, and the child swallows it, along with the constricted organ when the latter separates. It may be that tonsillitis was once common in the country, and the custom arose out of a determination to eradicate it by removing its seat. I gather that two members of my informant's family have suffered out there from the ailment. I forget where I first read of this practice; I cannot find any reference to it in any of the books at my disposal. Perhaps some of your readers may be able to supplement these scanty notes, for they seem to have a distinct bearing on "the use of the tonsils."

Toxic Plants.

A correspondent recently informed us that a patient had brought him a leaf, suspecting that it was the cause of an attack of conjunctivitis from which he was suffering. The medical man also handled the leaf, and shortly afterwards he himself was attacked with conjunctivitis. He ascertained that the plant belonged to the *Humea* family. We have made inquiries at the Royal Botanic Gardens, Kew, and the Director has been good enough to give us the follo[illegible] He says that it is not unusual for cases of [illegible] contact with leaves of *Humea elegans*, whic[illegible] plant referred to by our correspondent. Instances of injury by this plant, however, appear to be rarer than injury by contact with *Rhus toxicodendron* or *Primula obconica*. A very large number of people appear to be immune from the trouble caused by handling some or all of these plants. All have at one time or another given rise to skin irritation among the gardeners at Kew, though not every year. On one occasion two men and two women employed at the Royal Botanic Gardens were suffering at the same time from dermatitis caused by *Humea elegans*. A correspondent in "Gardening Illustrated" of July 29th, 1911, wrote: "I dread handling this *Humea*, as contact with the leaves quickly brings on severe inflammation of the eyes, which takes some time to recover from. Strange to say, although I have handled *Primula obconica* in large quantities, and in all stages, and have frequently trimmed up *Rhus toxicodendron*, I have never found any inconvenience from either of these." Against this a member of the Kew staff is very susceptible to poisoning from *Rhus toxicodendron*, but has suffered no injury from handling *Primula obconica* or *Humea elegans*.

Cane Sugar in Therapeutics.

Dr. G. C. Pether (Barnet) writes: Hive bees are sometimes fed during winter on syrup. It is asserted by some expert beekeepers that if beet instead of cane sugar is used in its preparation diarrhœa may result, whereas cane sugar is safe in this respect. Perhaps the Ministry of Agriculture could supply information concerning the difference between the two sugars. It is possible that the traditional objection to beet sugar for bee-feeding no longer holds good, the offending substance having, as Dr. Cameron suggests, been removed.

Ovariotomy after Seventy.

Mr. F. Herbert Wallace, F.R.C.S.Ed. (Uppingham), writes: Mr. Williams's account of ovariotomy in a woman over 70 years of age (*British Medical Journal*, April 13th, p. 679) prompts me to describe a similar case. The patient, an active married woman, aged 76, who had had eight children, the last when she was 45, first noticed an abdominal swelling in the summer of 1927, which increased somewhat rapidly during the last six months. She had considerable pain in the left hypochondrium, and wished to get rid of the swelling, as it impeded her in her household duties. On examination a tense and slightly tender swelling, proved to be due to the presence of an ovarian cyst, was found to reach the costal margin. At the operation the cyst was first evacuated by means of a suction pump, and then removed. Convalescence was uninterrupted; the patient was encouraged to move about in bed from the first, and she left hospital, walking well, on the twenty-first day. The cyst showed fairly recent haemorrhage into its interior.

Unusual Symptoms of Prostatic Enlargement.

"Risca" writes: I remember seeing an old lady a few years ago who was suffering from cancer of the cervix uteri; I found her busily soaking her feet in hot water, which, she said, gave relief from the troublesome pain and tingling she had in the soles. After attending to her I was requested to see her brother in an adjoining room, and was surprised to find him similarly engaged. On inquiry it became evident he was an old prostatic case, and that the pain in his feet was due to that trouble. The reason why the cervix and prostate appear to cause pain in the feet seems to be that the innervation of both is, through the sympathetic, by the posterior divisions of the sacral plexus, while the larger anterior divisions from the same root levels supply sensory nerves to the foot—that is, the pain is referred.

Vacancies.

Notifications of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 42, 43, 44, 45, 48, 49, and 50 of our advertisement [illegible] and advertisements as to partnerships, assistantships, [illegible] at pages 46 and 47.

[illegible] of vacant posts notified in the advertisement columns appears in the *Supplement* at page 203.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

491. The Semeiology of Dengue.

N. G. MACRIDI (*Rev. d'Hygiène*, April, 1929, p. 241) prefaces his report of an epidemic of dengue which occurred in Athens during 1927 and 1928 with some general considerations. In common with all epidemic diseases, dengue presents three periods of evolution: the onset, the stage of established disease, and the period of decline. The onset is sudden without prodromes, and the patient feels acutely ill. Fever, intense frontal headache, arthralgia, myalgia, renal pains, persistent insomnia, dryness of the mouth and pharynx, slight injection of the conjunctivae, and gastro-intestinal troubles are the usual primary symptoms. Bradysphygmia is an almost constant manifestation. Signs of respiratory involvement are absent, which differentiates the condition from influenza. The exanthem, which is often transitory and is sometimes preceded by an enanthem, usually appears on the third day on the neck, back, face, and inner surfaces of the arms. The fever drops on the appearance of the eruption, and then rises to its former level till the end of the attack, when it markedly falls, with profuse sweats. As the disease advances, haemorrhages (epistaxis, menorrhagia, haemoptysis, haematemesis, melaena, haematuria) appear. The gums become swollen and cyanotic; vomiting, sometimes bilious, is frequent, as is also complete anorexia and constipation. The teeth, especially carious ones, fall out, and alopecia is frequently present. Unilateral or bilateral parotitis occurs, and death often ensues from septicaemia following this complication. The respiratory apparatus is rarely involved, though slight laryngitis and pulmonary congestion may occur. Bradycardia is the rule, and the arterial pressure is usually lowered. Albuminuria is often considerable, with a notable diminution of urine. The urinary urea content is unaltered, but the blood urea is markedly increased. The changes in all the affected organs are due to muscle degeneration. The cardio-renal, associated with hepatic, insufficiency is a frequent cause of death from uraemia or eclampsia. The author adds that the virus of dengue is neurotropic, but the complications of the nervous system present no particular features. Convalescence is usually marked by melancholia and a diminution of the mental faculties for several days. Dengue is caused by a markedly virulent filterable virus conveyed by the female of a mosquito, the *Stegomyia fasciata* (*Culex fasciatus*).

492. Sterility in the Male.

L. W. MASON (*Amer. Journ. Obstet. and Gynecol.*, March, 1929, p. 376) discusses those cases of sterility in which no abnormality can be detected in the pelvis of the woman and motile sperms are present in the husband's semen. He urges careful handling in the preparation of slides to show undamaged sperms, and agrees with Moench that some sperms are double-headed while others are double-tailed. He shows that in the seminal fluid of husbands of sterile marriages abnormal sperms are more common, and a much greater variation exists in the length and diameter of the sperm head. Further observation reveals that certain sperms live longer than others in the same surrounding conditions; some specimens show no sperms alive three hours after ejaculation, while in others the sperms are alive at the end of sixty hours. It is concluded that normal sperms live for twenty-four hours under normal conditions of temperature, and that sperms reach the tube in three or four hours. Further investigation suggests that in those specimens where early death occurs the fault is inherent, and cannot be attributed to some hostile element in the prostatic, seminal, or even the vaginal secretions. The more protoplasm a sperm contains the longer it lives. Accordingly, in some cases the surviving sperms are megalosperms or abnormal in some other way; if the ovum is fertilized by such a one, an abnormal embryo is formed and abortion subsequently ensues. Mason suggests that this may be the cause of habitual abortion in some women. Kurzrok and Miller have obtained evidence that semen contains a ferment for the cervical mucus, and that in some seminal fluid this lysin is missing. There is also the possibility that the vaginal acidity may be the explanation of sperms reaching the external os. In some cases where husband and wife are normal the bar to conception is the plug of cervical mucus, and in these cases success has followed insemination about the twelfth day of the intermenstrual period, when, according to Frank, the female sex hormone is most plentiful in the urine.

493. The Etiology of Cardiospasm.

THOUGH the etiology of cardiospasm is obscure, H. W. SOPER and L. D. CASSIDY (*Amer. Journ. Med. Sci.*, March, 1929, p. 386) remark that a review of the literature reveals a remarkable unanimity among all observers that disturbances in the nervous mechanism of the cardia are responsible for the production of the spasm. The present authors concur in this view; they believe that the nervous mechanism controlling the cardia may be disturbed by a large variety of pathological conditions, and that the more closely cases are studied the more rarely will a diagnosis of idiopathic cardiospasm be made. A study of 60 cases of this condition was undertaken by the authors, in 29 of which some pathological conditions in other organs were found. Among the morbid processes associated with the spasm were gastric ulcer and carcinoma, duodenal ulcer, gall-stones, and exophthalmic goitre. The medical treatment of cardiospasm is considered to be useless, and surgery is rarely, if ever, indicated. The spasm yields readily to dilatation by either pneumatic or hydrostatic rubber-balloon dilators, the degree of dilatation depending upon the length of time the spasm has existed.

494. Sprue.

B. M. DEUTSCH (*Acta Universitatis Asiae Mediae*, 1929, Series IX, Medicina, Fasc. 3, p. 1) reports an outbreak of sprue among children in Turkestan. The clinical picture was characterized by an intestinal syndrome, haematological changes, and extreme emaciation with severe anaemia. The author states that in this infection meteorism and intestinal rumbling are pronounced; the tongue is cracked, the liver is atrophic, and the face is puffy. There is atrophy and fibrosis of the whole of the gastro-intestinal tract. The intestinal syndrome is characterized by diarrhoea, with profuse, frothy, acid, and putrid stools; under the microscope the presence of fatty acid and of yeast is easily discernible. The blood shows diminution of the red cells, leucopenia, lymphocytosis, and a normal or high haemoglobin index. In view of the hypocalcaemia and the acidosis Deutsch treated these patients with intravenous injections of calcium chloride, and obtained very good results.

Surgery.

495. Electrical Resection of Neoplasms.

E. N. KIME (*New England Journ. Med.*, March 14th, 1929, p. 532) records the end-results after treatment by "electro-surgery"—a term he prefers to surgical diathermy—in a series of 100 cases of malignant and premalignant neoplasms and infectious granulomata, all of which were operated upon more than a year previously. Though the time is too short to allow of definite conclusions, the results show that the method is of some value. In all the cases of recurrence except three a secondary electro-coagulation was employed with success. In many of the cases of failure, as well as of success, the patients had previously failed to respond to *x* rays or radium, or to both; Kime remarks that both these forms of treatment appear to be of value after rather than before an operation. In the author's procedure of "electro-surgery" a so-called cutting current of undamped or continuous oscillations produces in the tissues beneath the "acusector" a molecular disintegration with an electro-coagulative effect of the wound edges sufficient to seal the lymphatics and the blood vessels of moderate size. While insufficient penetration may allow a greater incidence of recurrence, this may be obviated by a judicious admixture of both the undamped and damped currents; as differentiated from electro-coagulation, this cutting current type of electro-surgery is not only more rapid, but allows of wound closure without drainage and with reasonable chance of primary healing. Kime stresses the point that though the method must be considered as competitive with scalpel surgery in the treatment of malignancy, it is safe only in the hands of an expert for use as an adjunct to, and not as a substitute for, ordinary surgical technique. In addition to sound surgical judgement and operative skill, its administration requires a practical knowledge of the principles underlying the application of the various types of damped and undamped oscillatory high-frequency currents for the electrothermic destruction of pathological tissues. The advantages claimed over ordinary surgery are: greater rapidity in operation owing to better haemostasis; its performance under local anaesthesia with

less chance of acidosis; a minimum of post-operative pain and shock; and, since the lymphatics are closed, less danger of septic absorption.

496. Epithelioma of the Suprarenal Cortex.

L. LANGERON, E. DECHERF, and DANES (*Bull. et Mém. Soc. Méd. des Hôp. de Paris*, April 1st, 1929, p. 436) report a case of suprarenal epithelioma in a young woman aged 20. The symptoms were amenorrhoea, virilism with hirsutism, hypertension, albuminuria and glycosuria, and considerable emaciation. The diagnosis was confirmed and the tumour localized radiologically, pneumo-peritoneum being also employed. The tumour was excised, but the patient died thirty-six hours later. In the absence of a post-mortem examination the actual cause of death was not ascertained, but it was ascribed to cardio-vascular reflexes caused by drawing on filaments of the sympathetic nerve during the operation rather than to suprarenal insufficiency. The relation between certain genital manifestations and tumours of the suprarenal cortex is well known, and the symptoms depend on the time of sexual life at which the tumours appear. When the tumour starts in intrauterine life suprarenal pseudo-hermaphroditism occurs. The external genitals are of masculine type, while the internal ones are really feminine. At puberty the secondary sexual characters are predominantly masculine, and the individual lives as a male. The suprarenal lesion is usually a simple hyperplasia or a benign adenoma, compatible with a normal survival. When the neoplasm occurs after birth it is usually malignant, and hirsutism with virilism develops. In girls, the most frequent subjects, an early development of the whole body, with an adult facies, obesity, hirsutism, and sometimes hypertrophy of the clitoris are noted. In boys the symptoms are obesity, very early puberty, pubic and facial hirsutism, and very marked muscular development, with hypersthenia. In young females amenorrhoea is the earliest sign, then appear obesity, glycosuria, hirsutism with virilism; a transient hypersthenia gives place to asthenia with emaciation, and death ensues from the malignancy or a pulmonary complication. At every age the tumour appears nine to eighteen months after the first symptoms, and rapidly grows until it fills the whole hypochondrium. Operation should always be performed in cases of these tumours, even if malignant, since the latter always terminate fatally if untreated. It is difficult to judge of the prognosis. Many writers have reported cure after operation, but the present authors are sceptical about this, especially in malignant cases.

497. Ligature of the Splenic Artery in Haemolytic Jaundice.

P. VALDONI (*Il Policlinico*, Sez. Chir., March 15th, 1929, p. 137) reports a case of haemolytic jaundice treated by ligature of the splenic artery. This is said to be the first case in which this treatment has been tried and the results were satisfactory; hitherto ligature of this artery has been chiefly tried in thrombopenia as an alternative to splenectomy, and good results have been obtained. Valdoni's patient, who was 22 years old, had suffered from birth with jaundice and progressive weakness; the liver and spleen were enlarged. The artery was ligatured under spinal anaesthesia; the jaundice slightly increased in the first week, but six weeks later the icteric tinge in the sclerotic had disappeared, there were no more attacks of pain in the spleen, the red corpuscles numbered 4,800,000, and the haemoglobin percentage was 50. Four months subsequently the general condition was excellent; there was no tiredness, and the weight had increased by 11 lb. There was a slight icteric tinge in the skin; the spleen was smaller, but was still enlarged, reaching the eighth intercostal space in the axilla. The result of the operation was not considered a complete success inasmuch as the jaundice and enlargement of the spleen still continued, but the patient's general condition was much improved. Valdoni describes also certain experiments made by him to determine the anastomoses which follow ligature of the splenic artery, and records the changes found in the blood after this operation.

498. Caecal Volvulus without Obstruction.

M. MAKKAS (*Zentralbl. f. Chir.*, March 30th, 1929, p. 786) has found records of 155 cases of this condition; in many of these the small intestine was involved also, but he reports a case in which this did not occur. A married woman, aged 33, had had one living child and one miscarriage. She was again three months pregnant, and was very exhausted by hyperemesis. One evening she had an attack of severe paroxysmal pain in the appendix region, the paroxysms lasting for two or three minutes; there was no abdominal rigidity nor borborygmi, but slight tenderness was noticed on pressure over the appendix region. The attacks persisted throughout the night. A diagnosis of atypical appendicitis was made and laparotomy was performed next day. The caecum lay in Douglas's pouch, behind the pregnant uterus. It was rotated clockwise upon its axis through 180 degrees. As the ileo-caecal valve was not involved there was no obstruction, but the intestinal wall was thickened and oedematous. Two days later vomiting returned, with severe acidosis, necessitating induction of abortion; the patient made a good recovery. Makkas states that among 42 cases of caecal volvulus in women, 10 of these patients were pregnant. He adds that the possibility of caecal volvulus simulating appendicitis should not be forgotten in cases in which the diagnosis is obscure.

Therapeutics.

499. Gold Salts in Pulmonary Tuberculosis.

As the result of four years' experience of using sanocrysin in the treatment of pulmonary tuberculosis, L. BERNARD and C. MAYER (*Bull. de l'Acad. de Méd.*, March 19th, 1929, p. 403) have come to the conclusion that, though the preparation is not a specific, it does exert a favourable action in this disease, particularly in acute types and in acute and progressing recrudescences. Of 142 acute cases, 62 (43 per cent.) showed improvement after gold treatment—a marked contrast to the less than 5 per cent. of spontaneous amelioration in cases from hospital records. The benefits produced by the gold salt were a fall of the temperature, a regaining of weight, improvement in the general condition, a diminution of the functional symptoms, and a slight amelioration of the physical signs. X-ray pictures showed changes; most frequently a sclerosis was noted, the shadows becoming more marked with a diminution in the extent of the lesions. This treatment was also followed in twenty-nine afebrile cases by excellent results, the improvement lasting from a few months to two or three years. Minor reactions which may be caused by the drug are a small rise in temperature, albuminuria, cutaneous troubles, and digestive disturbances, such as vomiting, abdominal pains, and slight diarrhoea. The treatment is contraindicated in cases of diarrhoea or albuminuria. In febrile cases 0.25 gram is injected during the first week, and 0.5 gram during the second. According to the general condition of the patient this dose is either continued or increased to 0.75 gram. The total amount injected varies from 5 to 7.5 grams. In afebrile cases 0.25 gram is given each week, and this dose should not be increased. Smaller doses should be administered on the resumption of treatment after temporary interruptions owing to unfavourable reactions. E. JEANSELME (*ibid.*, p. 411) reports good results from this drug in erythematous lupus. Starting with an initial dose of 0.1 gram, he increases it to 0.25 gram weekly; this dose is continued until cure results or signs of intolerance appear.

500. Liver Extract in Hypertension.

T. L. ALTHAUSEN, W. J. KERR, and T. C. BURNETT (*Amer. Journ. Med. Sci.*, March, 1929, p. 398) state that continued elevation of blood pressure definitely shortens life, and that the causes of death in hypertension are cardiac, including insufficiency, angina, or pulmonary oedema (46.7 per cent.), uraemic (22.6 per cent.), or cerebral (14.6 per cent.). A study of its effect on the kidneys, heart, and brain shows that the gradual reduction of pressure in hypertension cases is justified and reasonably safe. Since the work of Heidenhein in 1891 it has been known that many organic extracts, including that of the liver, were capable of lowering blood pressure. The active ingredient of liver extract responsible for this depressor effect is unknown, as is its mechanism; but it has been demonstrated that this extract acts independently of the vagus nerve and directly affects the blood vessels, especially those in the splanchnic area. As the result of a study of a series of cases of hypertension, the authors found that liver extract causes a considerable lowering of blood pressure, and affords complete or marked symptomatic relief in the majority of cases. The plan adopted was to inject 0.5 c.cm. three times a week, then 1 c.cm., gradually increasing the dose until at the end of two weeks 5 c.cm. are reached. The final dosage and frequency of administration depends entirely on the individual response. The extract was always injected intramuscularly into the arm and followed by massage of the part. No other treatment capable of influencing the blood pressure was given. After a single injection there was a fall in diastolic and systolic pressure lasting from two hours to a week; there was also in favourable cases a delayed but more lasting reduction following repeated injections. In eight cases the effect lasted from one to two and a half months after the injections were discontinued, and no acquired tolerance to the drug was noted. Age, sex, and the degree of hypertension proved to be immaterial in determining the success

of the treatment, and the presence or extent of cardiac damage was also of no significance. Arterio-sclerosis and its degree were of great importance in predicting the outcome; marked arterio-sclerosis influenced this unfavourably. The urinary findings had no certain bearing on the prognosis. The size of the dose did not affect the success or failure of treatment. No undesirable symptoms referable to the reduction of pressure were observed. Hypertension cases of under two years' duration, without marked arterio-sclerosis, and showing no fixation of specific gravity in the Mosenthal test, offer the best prognosis.

501. Treatment of Tuberculosis.

A. JOUSSET (*Presse Méd.*, March 16th, 1929, p. 353) discusses the treatment of tuberculosis by a bacillary emulsion termed "allergin," and describes in detail his method of preparing it. Allergin is described as an unstable and thermolabile colloid. In the normal healthy animal it excites an inflammatory reaction; it is said to be a good sensitizer, causes being l focal being excellent. Jousset considers that allergin is suitable for all cases of tuberculosis (medical, surgical, and dermatological) unless the patient is cachectic. Its subcutaneous injection is followed by a general reaction eight to ten hours subsequently, or later still in old-standing fibrotic cases; there is a corresponding elevation of temperature. According to the severity of this reaction the therapeutic dosage is regulated. A focal reaction occurs in which the cough, aphonia, and erythema are increased. The local reaction usually disappears in a few days. If, however, the patient is already allergic a necrosis may be produced. The author discusses the amount and frequency of the dosage.

502. Intraperitoneal Blood Transfusion.

W. C. C. COLE and J. C. MONTGOMERY (*Amer. Journ. Dis. Child.*, March, 1929, p. 497) submit a report of 237 intraperitoneal transfusions in 117 children ranging in age from 1 day to 4½ years. Citrated blood from a suitable donor was introduced by gravity, seldom more than five minutes being required to give 4 ounces. That was the usual amount for children under 3 years of age, the therapeutic effect from repeated small transfusions being as good as or better than from a single large one. No untoward effect is reported and reactions are minimized. The authors claim that this method has all the advantages of intravenous transfusion, except the replacement of blood volume. It finds its greatest usefulness in the treatment for secondary anaemia and in the combating of infection.

Anaesthetics.

503. Anaesthesia Produced by Barbituric Acid Compounds.

LATELY some authorities have reported great success in the anaesthesia obtained by the intravenous injection of some of the barbituric acid derivatives, especially with a combination of two hypnotics, di-ethyl barbiturate and allyl-isopropyl barbiturate. The drug is put up in 2 c.cm. ampoules containing 0.1 gram of each constituent in the form of a diethylamine salt, the solution being rendered stable by the addition of small amounts of alcohol and glycerin. J. H. FJELDE (*Anesth. and Analges.*, January–February, 1929, p. 40) discusses the use of this drug, known as somnifen, in obstetrics and surgery. Somnifen seems to act directly on the sleep centre, and is carried by the red cells, for which it has a special affinity. It is fixed with predominance in the nerve centres, is only very slightly retained by the liver, kidneys, and other tissues, and is eliminated unchanged by the kidneys. The drug in non-toxic doses has only a slight effect on the respiratory and cardiac centres; the blood pressure shows very little alteration; and the hepatic and renal functions are undisturbed. In obstetrical cases the drug is withheld until the contractions become painful, when it may be administered orally or intravenously. The average intravenous dose is 6 c.cm. and the anaesthesia lasts six hours; in large women the initial dose should be 8 c.cm. Oral administration is also very effective, and the action, though more gradual, is still comparatively rapid. The initial oral dose is 6 c.cm., and a further 2 to 4 c.cm. are given as required to prolong or deepen the effect. In surgery smaller doses, given only intravenously, are used. The usual surgical dose is 2 to 4 c.cm., depending on the size and susceptibility of the patient. Fjelde uses somnifen in intra-abdominal work, except in gastro-enterostomies or in enterostomies. It is especially valuable in goitre surgery; it has been used with excellent results in psychiatry and in cases, such as pneumonia, where rest is desired. The following are the advantages of somnifen according to Fjelde. In obstetrics it is without equal in the first and second stages of labour; during delivery additional anaesthesia must be used. Reflexes are maintained and labour pains are not lessened, nor is the amount of blood loss affected. The drug can be given in any stage of labour and maintained as long as may be necessary. It can be used in toxic conditions, has no late sequels, and only a very slight effect on the infant. In surgery, somnifen greatly reduces the use of ether, and it may be used with any form of inhalation anaesthesia. The drug increases the margin of safety by lessening the required amount of any other anaesthetic; it reduces post-operative distress and complications, and also the post-operative requirements for morphine.

504. Theory of Gas Anaesthesia.

P. TRENDELENBURG (*Narkose und Anaesthesie*, January 15th, 1929, p. 1) states that such narcotic gases as nitrous oxide, acetylene, ethylene, and propylene are theoretically superior to other anaesthetics because it is possible to avoid with certainty any overdose. The only essential is that an apparatus is used which ensures an exact dosage. The amount of the gas absorbed by the blood has been shown by Henry to depend directly on the tension of the narcotic gas contained in the anaesthetic mixture. How quickly the saturation of the blood necessary for narcosis is reached depends on the narcotic used. Gremels and Krayer, in experiments on themselves, found that the final nitrogen concentration in the alveolar mixture was reached in a few minutes. A narcotic gas, therefore, which has the physical quality of nitrogen only enters the blood in very small quantities and causes a deep narcosis in a few minutes. Narcotics such as propylene and ethylene, with the smallest solubility efficient, are nearest the ideal character of nitrogen, and at the same time exercise a high narcotic effect. The balance between the concentration in the blood necessary for the narcosis and the tension of the inspired air can be reached more quickly by the addition of carbonic acid to the air to be inspired.

505. Spinal Anaesthesia in Strangulated Hernia.

F. D. ALSINA (*Rev. med. de Barcelona*, February, 1929, p. 110) records his observations on thirty cases of strangulated inguinal and femoral hernia in patients aged from 20 to 78 operated on under spinal anaesthesia with only one death. The author remarks that the advantages of spinal over general anaesthesia are very definite. In the first place, it is much less toxic, and, secondly, it re-establishes instead of inhibiting peristalsis. Local anaesthesia has no action on the intestinal motility. The method used by Alsina is based on experiments which he performed on dogs. He found that spinal anaesthesia caused an almost immediate increase of intestinal peristalsis which lasted for a considerable time.

Obstetrics and Gynaecology.

506. Early Diagnosis and Prophylaxis of Cervical Carcinoma.

F. A. PEMBERTON and G. VAN S. SMITH (*Amer. Journ. Obstet. and Gynecol.*, February, 1929, p. 165) remark that long experience in the microscopical study of cervical tissue is necessary if one is to decide in a given instance whether cancer of the cervix is present or not. It is essential that the changes which occur in the cervical epithelium during the early active and later healing processes of cervicitis be clearly kept in mind. In the early stages of cervicitis ("erosion") the surface of the cervix is denuded, except in certain areas, of its squamous epithelium. Later, when a "pseudo-erosion" is formed, cylindrical epithelium grows down from the cervical canal and partially covers the bare area. Still later, as the inflammation subsides, the cylindrical epithelium loses its vitality and the squamous epithelium, proliferating underneath it, gradually forces it off. Occasionally the squamous epithelium plugs the duct of a gland, and the microscopical picture in cross-section is apt erroneously to suggest carcinoma. During the later stage of healing by regeneration of squamous epithelium gross areas of leucoplakia may be seen; hypertrophy may proceed to polyp formation; the squamous cells may show irregularity, especially in the transitional layers; occasional mitoses are found; and prolongation into the stroma and formation of epithelial pearls may occasionally occur. If these are tokens of a precancerous condition, the authors remark, then every lacerated or injected cervix is in a precancerous state. Pathologists differ as to when the boundary between benign and

malignant conditions is reached, but Pemberton and Smith feel justified in calling the condition one of early carcinoma when the squamous epithelium shows a basal layer which is undifferentiated from the transitional cells, consists of irregularly arranged cells with mitotic figures, has no basement membrane, and sends into the stroma prolongations surrounded by inflammatory infiltration. It is stated that of 669 cases of cancer of the cervix at the Boston Free Hospital 2.39 per cent. were diagnosed by microscopic examination. It is suggested that treatment of diseased cervices may be an important prophylactic measure as regards the incidence of carcinoma; none of 1,400 patients whose cervices were cauterized, none of 740 whose cervices were amputated, and only 5 out of nearly 4,000 patients in whom trachelorrhaphy was performed are known to have developed carcinoma. Similarly, of 669 patients with cervical carcinoma, none had had amputation or cauterization and only 12 had had trachelorrhaphy.

507. Diagnosis of Early Uterine Cancer.

E. NOVAK (*Journ. Amer. Med. Assoc.*, March 6th, 1929, p. 869) asserts that the most important single factor in cancer mortality is the duration of the disease, and that biopsy and diagnostic curetting, associated with competent pathological examination, are the procedures on which dependence must be placed for the recognition of early cases of uterine cancer. Any risk in these measures is more than offset by the valuable information they yield. Simple pelvic examination is not sufficient in these cases; biopsy should be employed in suspicious cervical lesions, and curetting in bleeding from the uterus of uncertain origin. Cervical lesions, such as erosions, endocervicitis, polypi, and ectropion associated with lacerations, are often difficult to differentiate from cancer. On the other hand, a cervical cancer in its earliest stages may appear as only a small, vascular, granular, sometimes indurated area on one or other cervical lip, and, when located at the external os, may differ little in appearance from a simple erosion. In such cases a conservative corrective operation should not be performed unless cancer is eliminated. Selected pieces of tissue should be removed by the knife rather than the cautery, and to avoid disseminating the cancer the edges of the small wound should be seared with the cautery. The most frequent single cause of uterine bleeding is incomplete abortion, others being myomata, hyperplasia of the endometrium, and cancer itself. Even if the uterus is the seat of myomata it must not be assumed that these are the cause of the bleeding, since adeno-carcinoma is of en associated with these tumours. Endometrial hyperplasia is a common condition which has been much overlooked until recently, and can only be differentiated from cancer by diagnostic curetting. Cancer of the body of the uterus is much less common and offers a better prognosis than the cervical type. Though usually occurring in women past the age of 50, in about 25 per cent. of cases it is found in those of the menstruating age. Bleeding in women past the menopause is suggestive of cancer. Ovarian tumours, and especially a certain type of cancer, are sometimes the cause of post-menopausal bleeding. Ovarian cancer of the granulosa type should always be suspected in haemorrhage after the menopause with a hyperplastic endometrium.

508. Biology of Chorion Epithelioma.

E. FELS (*Zentralbl. f. Gynäk.*, February 23rd, 1929, p. 466) found that small amounts of the serum or urine of a patient suffering from advanced chorion epithelioma of the uterus (twelve months after expulsion of a hydatidiform mole) contained in abundance the hormone of the anterior lobe of the pituitary, as demonstrated by the Zondek-Aschheim method of injection into infantile mice; much larger amounts of the urine failed to reveal, by the Allen-Doisy method of injection into castrated mice, the presence of ovarian hormone. Confirmation is given also of Aschheim's finding that the intrauterine fluid in hydatidiform mole is rich in the anterior pituitary hormone. Biologically these results, taken together with those of Zondek and Aschheim and of others, point to a similarity, as regards hyperproduction of anterior pituitary hormone, of (1) early pregnancy, (2) hydatidiform mole, (3) chorion epithelioma. Since the same hormone has been shown to be contained in the placenta, it may be inferred that chorion epithelioma has biological as well as histological similarities to placental tissue. Clinically the combination of hydatidiform mole or chorion epithelioma with the formation of large lutein cysts in the ovaries is not uncommon; such cyst formation is similar in many respects to the changes discovered by Zondek and Aschheim in the ovaries of infantile mice injected with anterior pituitary hormone, and it is possible, therefore, that the lutein cyst formation is due to excessive production of that hormone.

980 D

Pathology.

509. Oxygen Dissociation of the Blood in Graves's Disease.

H. ZONDEK (*Deut. med. Woch.*, March 1st, 1929, p. 345) considers that many forms of Graves's disease originate in abnormal metabolism at the periphery—that is, in the muscles. He has attempted to ascertain what part the secretion of the thyroid gland plays in the increased oxidation in the tissues, indicated by the raised metabolic rate found in all but the mildest cases during rest and exercise. Barcroft has shown that oxygen is normally more readily dissociated from the blood during and after work than before. Bansi, in collaboration with Zondek, found that the oxygen dissociation curve in Graves's disease is much lower than in normal individuals; the resting curve for subjects of this disease, in fact, resembles that found during muscular work in normal individuals—the oxygen appearing to be less firmly bound in the oxyhaemoglobin molecule in this condition than normally. On the other hand, in hypothyroid conditions, such as are found in some forms of obesity and in myxoedema, the resting curve shows that the oxygen dissociation capacity of the blood is diminished. Though many chemical reactions can be accelerated *in vitro* by the addition of ferments, it has never been possible to demonstrate that the thyroid hormone can act thus as an oxidizing catalyst. Zondek therefore considers it probable that thyroidin does not directly increase oxidation, but provides the conditions for increased oxidation. In the early stages of Graves's disease characterized by sweating and tachycardia, when the thyroid gland may not be appreciably enlarged, the oxygen dissociation curve of the blood is normal; only in the more severe cases is the dissociation curve altered. In the mildest cases, however, the output of the heart is increased during muscular work and also during rest. It is suggested that the oxygen tension in the tissues is abnormally high in early Graves's disease; that the blood therefore parts with its oxygen less readily; and that in order to remedy this the heart is stimulated to increased output before the increased thyroid activity facilitates the dissociation of oxyhaemoglobin.

510. Relation between Primary Infection and Clinical Manifestations in Tuberculosis.

O. SCHEEL (*Ann. Inst. Pasteur*, March, 1929, p. 394) has performed the cutaneous tuberculin test on 1,503 subjects in the rural district of Trysil in Norway. The curve depicting the percentage of positive reactors at different age groups was very like that obtained during a similar investigation of the inhabitants of Oslo, but was at a lower level. Thus in Oslo about 70 per cent. of the subjects in the 16 to 20 age group reacted positively, whereas in Trysil only 50 per cent. reacted. A very close relationship was found between the percentage increase in positive reactors and the reported number of cases of pleurisy. The maximum number of cases of pleurisy occurred in adolescents between the ages of 16 and 20, the maximum number of cases of pulmonary tuberculosis in subjects from 21 to 25 years old. The percentage of positive reactors in the 11 to 15 age group was about 27 per cent., in the 16 to 20 age group about 50 per cent., and in the 21 to 25 age group about 62 per cent. The author considers that the maximum number of cases of pleurisy and pulmonary tuberculosis occur at the time when there is a rapid increase in the percentage of positive reactors. In Oslo, Holmbeck found that among the infirmary probationer nurses 31 per cent. of those reacting negatively to tuberculin developed tuberculosis, while only 1.4 per cent. of those reacting positively did so. Taking these facts together the author concludes that in the great majority of cases pleurisy and pulmonary tuberculosis are manifestations of a recent primary infection.

511. A Rat Syndrome Resembling Pink Disease in Man.

AFTER the war cases of pink disease, or erythroedema polyneuritis, were described in this country, and the disease is now well recognized; the micropathology has been closely studied, but no light has been thrown on the etiology up to the present. M. FINDLAY and RUBY STERN (*Arch. Dis. in Childhood*, February, 1929, p. 1) describe the experimental production of a disease in young rats with the same pathological lesions by a vitamin-deficient diet. If dried egg white is the sole source of protein for a young rat a syndrome develops showing muscular weakness, redness of the animal's paws and face, and peripheral sensory neuritis. By feeding with raw potatoes, yeast, and raw albumin or yolk of egg, such a syndrome is prevented. The authors suggest that in the case of breast-fed infants suffering from pink disease a deficiency in the diet of the mother may be present, since they found that if the mother rat was on a vitamin-deficient diet her young developed pink disease.

GLAXO LABORATORIES

Glaxo House, London, N.W.1

THE scientific staff of the Glaxo Research Laboratories has amongst its duties to supervise and control the production and packing of all Glaxo, Ostelin, and Maltine lines, so that the Medical Profession may prescribe any of them, confident in the knowledge that the patient will receive an article of the highest possible efficacy and value—be it a matter of bacteriological purity, of chemical constancy, or of vitamin content.

OSTELIN PRODUCTS

"OSTELIN" IN GLYCERIN: 3 minims are equivalent in vitamin D value to one drachm of cod-liver oil. Valuable for dispensing.

DOSE.—CHILDREN: 1–4 drops t.d.s.p.c.
ADULTS: 2–10 drops t.d.s.p.c.

OSTOMALT: "Ostelin," malt extract, and orange juice; contains calcium glycerophosphate. An unrivalled means of providing vitamins A, B, C, and D.

DOSE.—CHILDREN: 1 teaspoonful t.d.s.p.c.
ADULTS: 1–3 teaspoonfuls t.d.s.p.c.
INFANTS: If bottle fed ½ to ¾ teaspoonful with one or more feeds.

"OSTELIN" with PARATHYROID TABLETS: Sugar-coated tablets, containing equivalent to 3 minims "Ostelin" in glycerin, two grains of calcium glycerophosphate, and one-fortieth of desiccated parathyroid.

DOSE.—One tablet two or three times a day.

"OSTELIN" EMULSION: Contains "Ostelin" equivalent in vitamin D value to 50% cod-liver oil, with calcium glycerophosphate.

DOSE.—INFANTS: ½ teaspoonful in the food once to six times daily, according to age.
OLDER CHILDREN: One teaspoonful t.d.s.p.c., plain or in milk.
ADULTS: 1–3 teaspoonfuls t.d.s.p.c.
TO BREAST-FED CHILDREN: The Emulsion should be given by spoon.

"OSTELIN" TABLETS: The most suitable form for adults. In all hypotonic conditions and wasting conditions generally. Contains calcium glycerophosphate.

DOSE.—1–4 tablets t.d.s.p.c. As a prophylactic, 2 tablets twice a day.

ELIXIR "OSTELIN": When diluted 1 to 7 is equal in vitamin D potency to the finest medicinal cod-liver oil.

DOSE (Undiluted).—ADULTS: 10–30 minims.
CHILDREN: 5–15 minims, according to age.

Also "Ostelin" Ampoules for intramuscular injections.

MALTINE PRODUCTS

MALTINE with PEPSIN and PANCREATIN: Containing the three principal digestants—Diastase, Pepsin, and Pancreatin—in such proportions as to be capable of converting all foods required by the human organism into the soluble condition necessary for proper assimilation.

MALTINE (*Plain*): Differs from ordinary malt extract in containing the concentrated elements of wheat and oats in addition to barley, and being in the form of a thin syrup, with a diastatic strength (1000 B.P.C.).

MALTINE with CREOSOTE: Each fluid ounce contains 4 minims of Creosotum B.P. Indicated in Tuberculosis, especially pulmonary, and in septic conditions of the alimentary canal.

MALTO-YERBINE: A stimulating expectorant combining the nutrient properties of Maltine with the expectorant soothing properties of Yerba Santa (Eriodictyon Californicum).

MALTINE with CASCARA SAGRADA: Each fluid ounce contains one and a half drachms of Liquid Extract of Cascara Sagrada B.P. *Specially valuable in post-natal conditions, as it* provides the safe, gentle laxative required to restore the interrupted habit of intestinal regularity.

MALTINE with COD-LIVER OIL: Maltine (full diastatic strength) 70 per cent., Pure Norwegian Cod-Liver Oil 30 per cent. A perfect emulsion, palatable and easy of assimilation.

SUNSHINE GLAXO

with added vitamin D

Sunshine Glaxo (in the white tin) contains "OSTELIN." This added vitamin D prevents rickets and ensures sound bones and teeth. It not only enhances the value of the food for infant feeding, but also makes it a most beneficial food for expectant and nursing mothers.

Undoubtedly one result that has come from adding vitamin D to the New Glaxo has been—no constipation. The importance of this cannot be emphasised too much.

FOR EXPECTANT & NURSING MOTHERS the quantity of Sunshine Glaxo recommended is: twice daily, two tablespoonfuls to a breakfast cup, adding water just off the boil.

Any request for further information should be addressed to Glaxo Laboratories, London, N.W.1

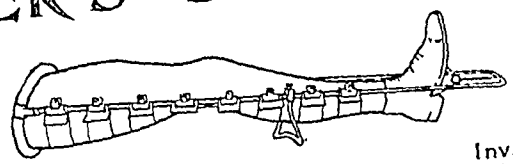
COLLENDER'S SPLINTS

(Patented in many Countries)

Combine the advantages of the Thomas Splint with many improvements and additions.



They are supplied in fitted cases. The larger set provides material for treating ten fractures simultaneously.

Advantages:

They ensure accurate extension and safe transport. They are adjustable to any length of limb. All parts are interchangeable, standardised, numbered, and replaceable. Being made of metal—Duralumin—they combine great strength with very light weight. They are untarnishable, and can be immersed in sterilizing fluid without injury. They can be used repeatedly.

Invaluable for

Hospital Emergency work, particularly to District Surgeons, Mines, Ranches, Lumber Camps, Railways, Shipping Companies, Industrial Plants, and all places remote from surgical help.

Full particulars from:

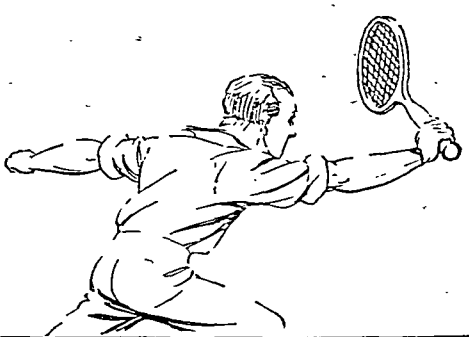
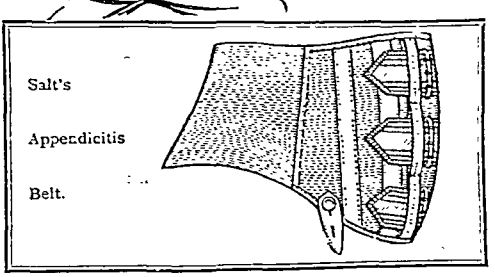
Salt and Son Ltd.

Salt's specially light Appliances for SUMMER WEAR





Outdoor exercise during the summer months demands a seasonal change in the type of appliance worn just as much as in clothing.

Salt's specially light appliances for Summer Wear

provide a lightness (while ensuring proper support) that affords complete freedom in bodily movement.

Apart, however, from such a consideration are the questions of economy and personal cleanliness, the wearing of a Salt's summer appliance enabling the patient to release the ordinary appliance for the necessary cleaning and repairing.

"The Rose Corset-Belt"

for Accurate Abdominal Support and Comfort

EXTRACT FROM THE "BRITISH MEDICAL JOURNAL," DEC. 10th, 1927—

"Visceroptosis is the cause of so much discomfort and ill-health . . . and an ill-fitting or wrongly applied belt or corset may aggravate rather than diminish the subjective effects of this condition. . . . MADAME ROSE has for many years devoted special attention to this problem, and we have good reason to believe that she has given help and comfort to a considerable number of sufferers. We have received assurances from medical men, who have sent patients to her, that she gives personal attention to each patient, that she takes great care in adapting and adjusting the support to the particular needs of the case."

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical baths, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The Seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone: No 56 Northampton), who can be seen in London by appointment.

EDWIN DELLER, Academic Registrar.

Workmen's Compensation Act, 1925.

MEDICAL BOARD FOR SILICOSIS.

It has been arranged between the Home Office and the industries concerned that the periodic and other medical examinations required under the Refractories Industries (Silicosis) Scheme, 1925, and the Sandstone Industry (Silicosis) Scheme, 1929, shall be carried out by a joint Medical Board, the members of which will be allotted to certain centres, and which will have its central office at Sheffield. The Home Secretary proposes to nominate at once, in addition to the two ... Medical Officers already working u... Scheme, TWO ... Members of the MEDICAL ... Board.

The duties of the Medical Board, which are fully explained in the First Report of the Departmental Committee on Compensation for Silicosis, are to visit the different areas in which the Refractories and Sandstone Industries are carried on and to carry out jointly the periodic and other examinations and grant the necessary certificates under the two Schemes.

The scale of salary of the additional officers will be £750, rising by £25 a year to £900. The appointments will be for a definite term—not less than three years—and will be capable of renewal, but will be subject to termination at the discretion of the Secretary of State. Travelling expenses and subsistence allowances will be paid.

The salaries and expenses of the Medical Board are payable by the Refractories and Sandstone Industries Compensation Funds, but the Board work under Instructions issued by the Secretary of State and are directly responsible to him.

Further particulars and forms of application may be obtained from the Industrial Division, Home Office, Whitehall, S.W.1.

Applications should be made not later than May 31st.

Home Office,
Whitehall, S.W.1. May 7th, 1929.

Applications should be sent to the Secretary, from whom further particulars can be obtained, not later than June 1st.

Northamptonshire.

TUBERCULOSIS OFFICER.

The Northamptonshire County Council invite applications for the appointment of Tuberculosis Officer.

The salary will be at the rate of £750 per annum, together with offices, clerical assistance, stationery, and such allowances for travelling and other necessary out-of-pocket expenses as the County Council shall from time to time approve. A periodical review of salaries is made by the County Council, and suitable increments of salary will be given for proved ability and satisfactory service.

The salary will be subject to a deduction of 5 per cent. per annum for superannuation, in accordance with the provisions of the Local Government and Other Officers Superannuation Act, 1922, which the County Council have adopted. The candidate appointed will be required to pass a medical examination.

The officer appointed must reside at a place to be approved by the County Council and devote the whole of his time to the service of the Council.

The officer appointed will be independent clinically, but administratively is on the staff of the Public Health Department under the County Medical Officer of Health. The duties include the charge of the Tuberculosis Dispensaries, and of the care, otherwise than in sanatoria, of persons suffering from or suspected of tuberculosis. The Council maintains its own sanatorium and a Resident Medical Officer is in charge thereof.

The appointment is subject to the approval of the Ministry of Health, and is determinable by three months' notice on either side.

Applications, endorsed "Tuberculosis Officer," with not more than three recent testimonials, giving full particulars of the training, qualifications, experience, and age of the applicant, should reach the undersigned on or before June 7th. Six copies of the application and testimonials should be supplied for the use of the Committee.

Canvassing will disqualify.

County Hall, H. A. MILLINGTON,
Northampton. Clerk of the County Council.

City of Aberdeen.

The office is an established post under the Local Government and Other Officers Superannuation Act, 1922, and the successful candidate will be required to pass a medical examination.

Applications, accompanied by twenty copies of testimonials, and endorsed "Medical Officer of Health," to be lodged with the undersigned not later than 31st instant.

G. S. FRASER,
Town House, Town Clerk.
Aberdeen.
May 9th, 1929.

County Borough of Derby.

TEMPORARY ASSISTANT MEDICAL OFFICER (Male).

Applications are invited for the post of Temporary Assistant Medical Officer in the Public Health Department, for a period of four months. Duties will include those of Assistant School Medical Officer, Assistant Tuberculosis Officer, and such other work as the Health Committee and Medical Officer of Health may require.

Applications, stating age, experience, and qualifications, together with copies of not more than two recent testimonials, to be sent to the undersigned. Salary at the rate of £600 per annum.

ALBERT E. BRINDLEY,
Medical Officer of Health.

East Ham Memorial Hospital,

Shrewsbury Road, E.7.

Applications (male) are invited for the following:

1. RESIDENT MEDICAL OFFICER;
2. RESIDENT HOUSE PHYSICIAN and CASUALTY OFFICER.

The appointments are for six months as from July 1st next, with salaries at the rate of £150 and £100 per annum respectively, with board, residence, and laundry. Application, stating age, experience, and full particulars, together with copies of testimonials, should be sent to the undersigned not later than Friday, June 7th.

J. F. MORTON, Secretary.

Nottinghamshire.

ASSISTANT MEDICAL OFFICER FOR SCHOOL MEDICAL INSPECTION AND FOR MATERNITY AND CHILD WELFARE.

Applications for the above-named appointment are invited from duly registered medical practitioners who have had at least three years' experience since obtaining registrable qualifications, and who hold a Diploma in Public Health.

Preference will be given to candidates with previous experience of the work, particularly as regards Mental Deficiency, Refractions, and Ante-natal work.

The salary will be at the rate of £600 per annum, with travelling expenses in accordance with the County Council Scale. The appointment will be a whole-time one. The candidate appointed will be a member of the Staff of the County Medical Officer, will work under his control and direction, will be required to reside in a part of the County to be approved by him, and to carry out such duties as may be prescribed.

The successful candidate will be required to pass a medical examination.

Forms of application may be obtained from the undersigned, and should be returned, accompanied by copies of not more than three recent testimonials, to the County Medical Officer, Shire Hall, Nottingham, on or before May 30th.

Shire Hall, Nottingham. K. TWEEDALE MEABY, Clerk of the County Council.
May 14th, 1929.

Nottinghamshire.

ASSISTANT COUNTY MEDICAL OFFICER OF HEALTH.

Applications are invited from duly qualified and registered medical practitioners (male) for the appointment of Assistant County Medical Officer of Health. Candidates must have had previous experience of the general administration of a Public Health Department (preferably of a County Council) and possess a Diploma in Public Health. Experience of the administration of School Medical Inspection, Tuberculosis, and Child Welfare Services, together with a knowledge of special Mental Deficiency Examinations and the carrying out of Refractions, will be deemed additional qualifications.

The person appointed must devote the whole of his time to the duties of the office. He will act under the control and direction of the County Medical Officer as his Chief Administrative Assistant, will carry out such duties as the County Medical Officer may assign to him from time to time, and will be required to reside in a part of the County to be approved.

The salary will be at the rate of £750 per annum, rising, subject to satisfactory service, by annual increments of £25 to a maximum of £800 per annum, with travelling expenses in accordance with the County Council Scale, and the appointment will be terminable by three months' notice, in writing, on either side.

The selected candidate will be required to pass a medical examination.

Forms of application may be obtained from the undersigned and should be returned, accompanied by copies of not more than three recent testimonials, to the County Medical Officer, Shire Hall, Nottingham, on or before May 30th.

Shire Hall, Nottingham. K. TWEEDALE MEABY, Clerk of the County Council.
May 14th, 1929

Stoke and Wolstanton Union.

ASSISTANT MEDICAL OFFICER (Male).

Applications are invited for the appointment of First Assistant Resident Medical Officer at the LONDON ROAD INSTITUTION, near NEWCASTLE, STAFFS.

The remuneration assigned to such office is £250 per annum, with board and residence. The period of the appointment will be limited to one year in the first instance, subject to termination by one month's notice on either side. The Institution accommodates about 1,000 inmates, including 600 in hospital (which is recognized as a major training school for nurses) and 150 in mental wards. The medical service to the adjacent Children's Homes is performed by the Institution Resident Staff, who, also, are required to lecture to nurses.

Applications, accompanied by copies of not more than three testimonials of recent date, should be delivered to the undersigned not later than first post on Thursday, the 30th instant. Applicants should state particulars of qualifications or degrees held, the date thereof, when then, and experience since qualifying. Preference will be given to those who have had experience in any of the following subjects—viz., Anæsthetics, Obstetrics, Pathology, and Radiography.

Union Offices, High Street, Stoke-on-Trent. T. WOOD, Clerk to the Guardians.
May 17th, 1929.

County Council of Middlesex.

DENTAL SERVICE.

ASSISTANT DENTAL OFFICER.

The County Council invite applications for the post of Assistant Dental Officer. Applicants must be fully qualified and registered Dental Surgeons.

The duties of the post are the dental inspection and treatment under the Education and Maternity and Child Welfare Acts.

The candidate appointed will be required to devote his or her whole time (including Saturday mornings) to the duties of the post, will not be allowed to engage in private practice, will be under the supervision of the County Medical Officer and the Senior Dental Officer, and must be prepared to reside in such district as may be required.

The officer appointed will be entitled to one month's holiday annually.

Salary £500 per annum, rising by annual increments of £25 to £700. (No bonus.)

The appointment will be during the pleasure of the Council, and subject to one month's notice on either side.

The successful candidate will be required to pass such medical examination as the County Council may direct, and to contribute to the County Council's Superannuation Fund.

Applications, setting out (1) age, (2) qualifications, and (3) experience, together with copies of three recent testimonials, should be forwarded to the undersigned so as to reach this office not later than June 1st. No special application forms are provided.

Canvassing will disqualify.

Middlesex Guildhall, Westminster, S.W.1. ERNEST S. W. HART, Clerk of the County Council.
May 10th, 1929.

Walsall and West Bromwich UNIONS JOINT COMMITTEE.

APPOINTMENT OF RESIDENT MEDICAL OFFICER.

The Committee invite applications from fully qualified male resident medical practitioners for the appointment of Resident Medical Officer for the Institutions at GREAT BARR PARK. The Institutions consist of Children's Homes for approximately 100 children under the age of five years, and a Mental Defective Colony. The number of patients at present at the Colony is approximately 300. This number will be increased to 600.

Preference will be given to candidates who have had previous experience with mental defectives.

The Resident Medical Officer will be responsible to the Visiting Consulting Medical Officer so far as the Children's Homes are concerned, and the Visiting Consulting Medical Officer attends when required at the Colony.

Commencing salary £500 per annum, together with furnished quarters, rations, laundry, and attendance.

The officer appointed must devote the whole of his time to the duties, and the appointment will be terminable by three months' notice on either side.

Canvassing, either directly or indirectly, is strictly prohibited and will be deemed a disqualification.

Applications, stating age, experience, and qualifications, accompanied by copies of not more than three recent testimonials, must reach me not later than Saturday, June 1st.

By Order,
22, Lombard St., West Bromwich. A. H. WARD, Clerk.
May 18th, 1929.

Kingston Union.

APPOINTMENT OF THIRD ASSISTANT RESIDENT MEDICAL OFFICER.

The Guardians of the Poor of the Kingston Union require a thoroughly qualified Third Assistant Resident Medical Officer at the Kingston and District Hospital (age not to exceed 30 years).

The appointment will be for six months in the first instance, and may be extended, subject to satisfactory service.

The salary will be at the rate of £250 per annum, with apartments, rations, laundry, and attendance (valued at £100 per annum for superannuation purposes), and will be subject to the terms of the Poor Law Officers Superannuation Act, 1896.

Applications for the post, stating age, experience, and nationality, together with recent testimonials, should reach me not later than 10 a.m. on Friday, May 31st.

Experience in administration of anæsthetics essential.

Canvassing, either directly or indirectly, will disqualify.

Union Offices, Kingston-on-Thames. W. TAYLOR, Solicitor, Clerk to the Guardians.
May 14th, 1929.

Lancashire County Council.

SCHOOL MEDICAL AND CHILD WELFARE DEPARTMENT.

APPOINTMENT OF THREE ASSISTANT COUNTY MEDICAL OFFICERS.

The Lancashire County Council invite applications from registered medical practitioners for the post of Assistant County Medical Officer.

Applicants must not be over 35 years of age, and must possess the Diploma of Public Health.

The duties of the post include the Medical Inspection of School Children; work under the Maternity and Child Welfare Acts; general Public Health work; and such other duties as may from time to time be imposed by the County Council.

The persons appointed will be required to devote their whole time to the service of the County Council. The salary will be £800 a year, rising (subject to satisfactory service) by annual increments of £50 to a maximum of £1,000 a year, together with first-class railway fares and other reasonable expenses.

The persons appointed will be required to pass a medical examination, and to contribute to the Council's Superannuation Fund.

Applications must be made upon a form which can be obtained, together with further particulars, from the County Medical Officer of Health, School Medical and Child Welfare Department, County Offices, Preston, to whom the completed forms should be returned not later than Saturday, June 15th. All communications must be endorsed "Assistant County Medical Officer."

Any form of canvassing is strictly forbidden, and will disqualify.

County Offices, Preston. GEORGE ETHERTON, Clerk of the County Council.

LOCUM TENENS MEDICAL OFFICER (male) wanted for about 13 weeks, beginning June 30th. Salary 7 guineas per week, together with residence, board, and laundry. Applications, stating age, qualifications, nationality, and copies of recent testimonials, to be sent to the Medical Superintendent.

Urban District Council of BARKING TOWN.

ASSISTANT MEDICAL OFFICER.

Applications are invited from qualified medical practitioners (preferably women) for the combined appointment of Assistant Medical Officer of Health and Assistant School Medical Officer under the Public Health and Education Committees of the above Council. The officer appointed will be required to devote his or her whole time to official duties and to reside within the district. The principal duties will consist of maternity and child welfare and school clinic work and the medical inspection of school children, to be carried out under the direction of the Medical Officer of Health, who is also the School Medical Officer. The appointment will be subject to one month's notice on either side. Salary £500 per annum, inclusive of all bonus, rising after one year's satisfactory service to £600 per annum.

The person appointed will be required to pass a medical examination and to contribute to the Council's Superannuation Fund.

Forms of application may be obtained from the undersigned, to whom they should be returned, endorsed "Assistant M.O.H.," with copies of not more than three recent testimonials, not later than June 7th.

H. HARGREAVES,
Public Offices, Clerk to the Council.
Barking.
May 17th, 1929.

Leicestershire County Council.

ASSISTANT COUNTY MEDICAL OFFICER OF HEALTH.

Applications are invited from duly qualified registered medical practitioners (male) for the appointment of Assistant County Medical Officer.

Candidates must possess a Diploma in Public Health; experience in School Medical Inspection and Tuberculosis work will be deemed an additional qualification.

The person appointed must devote the whole of his time to the duties of the office and will carry out such other duties as the County Medical Officer may assign to him.

The salary will be at the rate of £650 per annum, rising, subject to satisfactory service, by annual increments of £25 to £700 per annum, with travelling expenses according to the County Council scale.

The appointment is subject to the Local Government and Other Officers Superannuation Act, 1922.

The appointment will be terminable by three months' notice on either side.

Forms of application may be obtained from the undersigned, and should be returned, accompanied by copies of not more than three recent testimonials, by Monday, June 3rd.

W. J. FREER,
10, New Street, Clerk of the Council.
Leicester.
May 18th, 1929.

Salop County Council.

MEDICAL INSPECTION OF SCHOOL CHILDREN AND MATERNITY AND CHILD WELFARE.

Applications are invited from registered (male) for the post of . . . . OFFICER to work under £600 per annum, rising by annual increments of £25 to a maximum of £700, with travelling and out-of-pocket expenses on a fixed scale.

The salary will be subject to a deduction of 5 per cent. for Superannuation under the Local Government and Other Officers Superannuation Act, 1922, and the candidate selected will be required to pass a medical examination.

Candidates must possess a Diploma in Public Health, and experience in Refraction work will be considered an important additional qualification.

Applications should be received on or before Saturday, June 8th, by the County Medical Officer of Health, College Hill House, Shrewsbury, from whom forms of application, conditions of appointment, list of duties, and any other information can be obtained.

Blackburn and East Lancashire ROYAL INFIRMARY.

FOURTH HOUSE SURGEON (male) required for Casualty Department, etc., at a salary of £130 per annum, with board, residence, laundry, etc.

The Hospital contains 240 beds, with X-ray, Massage, V.D., Eye, Ear, Nose, and Throat Departments, Pathological Laboratory, etc. There is no outside work.

Applications, with copies of testimonials, stating age, nationality, experience, etc., to be sent at once to the undersigned.

NATHAN A. SMITH,
Royal Infirmary, Gen. Supt. & Secretary.
Blackburn.

County Borough and Port of GRIMSBY.

ASSISTANT MEDICAL OFFICER OF HEALTH.

Applications are invited for the above appointment from medical men. Applicants must be duly qualified and registered practitioners of at least three years' standing, and possess the Diploma in Public Health.

The duties will be chiefly in connection with Tuberculosis, but the successful candidate will be required to undertake duty in any such of the Health Services, including the Port (Inspection of Aliens).

Candidates must have had experience in Tuberculosis work, and preference will be given to those who have held a resident Hospital appointment (General, Sanatorium, or Fever). Salary £700 per annum.

Application, stating age, qualifications, and experience, accompanied by copies of three recent testimonials, should reach me, endorsed "Assistant Medical Officer of Health," not later than June 10th.

British Medical Bureau

(THE SCHOLASTIC, CLERICAL & MEDICAL ASSOCIATION LTD.)
(FOUNDED 1880.)

12, Stratford Place, Oxford Street, W.1.

Tele. Address: Triform, Wes'lo—London. Telephone: Mayfair {1782 1783

The Association has long been favourably known to the members of the Medical Profession as a thoroughly trustworthy and successful Agency for the transaction of every description of Medical, Scholastic and Accountancy business, and the BRITISH MEDICAL ASSOCIATION has every confidence in recommending its members to consult Mr. A. V. STOREY, the General Manager, in all transactions requiring the services of a Medical Agent.

Members of the British Medical Association may take advantage of a reduced scale of charges applicable to them.

The business undertaken by the British Medical Bureau is divided under the following heads:—

TRANSFER OF PRACTICES, PARTNERSHIPS, etc.

Medical Practitioners wishing to dispose of Practices, or desiring to take Partners, are advised to negotiate the business through the British Medical Bureau. Vendors may depend upon receiving introductions only to eligible and bona-fide purchasers. All information is treated in strictest confidence.

Full and trustworthy information regarding Practices, Partnerships, etc., for disposal, supplied gratis to Purchasers.

ASSISTANTS AND LOCUMTENENTS.

Assistants and Locumtenents can be secured at short notice. It is the foremost aim of the British Medical Bureau to ensure that only the most Trustworthy and Reliable Locums and Assistants are sent out.

RESIDENT PATIENTS.

Medical Men wishing to receive Resident Patients should enrol their names on the books of the British Medical Bureau. A large number of Patients are placed yearly through this medium.

ACCOUNTANCY.

The British Medical Bureau has its own staff of fully qualified Accountants wholly engaged on medical work—i.e., Investigation of Practices for purchasers, Income Tax, Auditing Books & Accounts, etc.

ALDINE HOUSE,

10-13, BEDFORD STREET, STRAND, LONDON, W.C.2.

Telegrams: BOVMEDICAL, WESTRAND-LONDON. *Telephone*: GERRARD 3543 (3 Lines).

Under the personal direction of Dr. J. FIELD HALL and Mr. J. C. NEEDES

who have both had many years' experience as Medical Transfer Agents.

The commission chargeable in respect of any practice or partnership in Great Britain placed exclusively in the hands of this Agency has been fixed on an exceptionally favourable scale, the maximum chargeable on any transfer being fifty pounds (£50).

No charge is made to Principals for the introduction of Locum Tenens or Assistants. Accountancy and legal services furnished by the Agency, where desired, at moderate inclusive charges.

1. WITHIN 50 MILES OF LONDON.—In a small Country Town, in pretty district, a well-established increasing PRACTICE, worth last year over £800, including panel of 525, and appts. about £60. Visits 3/6 to 21/-, medicine extra. Midwifery discouraged. Railway station in place. Very good house (3 reception, 5 bedrooms, etc.), with large garden. Tennis court. Garage. Electric light. Price for freehold £3,100. *Premium 1½ years' purchase.* Exceptionally good educational facilities for boys.
2. WORCS.—COUNTRY PRACTICE, near large town.—Very old-established good mixed Practice in attractive district. Average income for past three years £1,027, including panel of 560, and appts. worth over £60 p.a. Fees 2/6 to 10/-. About 30 cases of midwifery 2 and 3 gns. House is very well situated, and contains 2 reception, 5 bedrooms, etc., and separate professional rooms. Good garden. Garage for 2 cars. Price for freehold £2,000, half on mortgage. Excellent sport. Premium £1,350.
3. DEATH VACANCY.—NORTHANTS.—PRACTICE is situated in a *country district, near large town.* It is a mixed-class one, producing about £1,200 p.a., including panel of 800. Fees 3/6 to 10/6, *with medicine extra.* About 20 cases of midwifery from 2 to 5 gns. Very good house can be bought, or purchaser can choose his own place of residence, renting the present professional rooms. Premium one year's purchase. Efficient Locum in charge.
4. CARDIFF. — Good-class old-established *non-dispensing* PRACTICE, worth last year about £1,400, including select panel of 450. Visits up to 21/-. Very little midwifery. Good house in best part of City, with ample accommodation. Price, freehold, £2,000. Prem. £2,000.
5. PLYMOUTH.—Old-established and increasing mixed-class PRACTICE, *worth last year nearly £2,000* (at rate of £3,000 for first 3½ *months* of this year), including appts. worth £140 and panel of 1,100. Visits 3/6 to 21/-. Midwifery 3 to 5 gns. (60 to 80 cases yearly. Convenient house (professional accommodation, 2 reception, 4 bedrooms, etc.) on long lease at £80 a year. Premium £3,000. Efficient introduction given.
6. WITHIN 60 MILES OF LONDON.—Unopposed very old-established *easily worked* PRACTICE, in pretty country district about 5 miles from Hospital Town. Cash receipts last financial year £1,552 (shows considerable increase for last 9 months), including appts. and panel (nearly 1,200) £899. Visits 3/6 to 10/6, medicine extra. Practically no midwifery. *Excellent modern freehold residence* (bathroom, electric light, system drainage, etc.), with ample accommodation. Garden. Garage. Price £3,300, £2,300 can remain on mortgage. Premium £2,400, to include drugs, etc. Good hunting, shooting.
7. FAVOURITE INLAND SPA.—PARTNERSHIP.—A well qualified experienced gentleman (aged about 40, married, and good at Gynæcology) is required to purchase the half share of an old-established good-class non-dispensing Practice owing to the retirement through ill health of the senior partner. *Income about £5,000, including small select panel.* Good number of midwiferies. Suitable house available, with ample accommodation, at low rental. Premium 2 years' purchase.
8. *SOUTH LONDON (NEAR CROYDON).—Sound and increasing* mixed-class PRACTICE, in growing locality. Gross cash receipts for immediate past 12 months £2,800, including panel of 2,240. Fees 2/6 to 7/6. Convenient freehold house, with electric light. Garage. Garden. Good sport and schools. *Premium £4,500. Efficient introd.*
9. PARTNERSHIP, with ultimate succession.—SOUTH-WEST LONDON.—A third or half share, to commence with, in an old-established *good mixed non-panel* Practice, offering large scope. Receipts for last year nearly £2,500. Fees 2/6 to 7/6. Little midwifery. Good house, with garden. Can be obtained on long lease at the very moderate rent of £55 p.a. Premium 2 years' purchase.
10. *MIDLANDS.—Country district, near* large Town.—Agricultural and working-class PRACTICE, rapidly increasing. Income last year £1,250, including panel of 545. Visits 3/6 and 5/-. Small convenient house, freehold. Price, including all furniture, excepting linen and plate, £1,650 (*£1,000 on mortgage at 4 per cent.*). Large garden. Garage. Excellent sport. Premium £1,800.
11. LANCS.—COAST TOWN.—Old-established better and middle-class PRACTICE. Income for 1928 over £1,200. Panel of 556. Visits from 4/-. Well situated house in residential district. Price for freehold £2,700, £1,500 on mortgage. Premium £1,800, £1,000 down and balance by instalments.
12. *SOUTH AFRICA.—Well-established* PRACTICE, in small pleasant Town (nearly 5,000 ft. above sea-level in midst of very prosperous and rich district. Receipts last financial year £2,198, including appts. worth £80. Opposition (one) weak. Bungalow residence containing 2 consulting rooms, surgery, 2 sitting, 2 bedrooms, bathroom, etc. Small garden. Garage. Price, freehold, £500; £200 can remain on mortgage. *Premium £1,200, to include drugs, instruments, surgery* and other furniture and effects in house. Climate excellent. Educational facilities and sport. Splendid opening for surgery.
13. NEW ZEALAND.—(North Island).—In an up-to-date Town (pop. 12,000, with a further 10,000 in outlying district) within 12 miles of the sea, a well-established PRACTICE worth last year over £1,000, including appts. averaging £280. Visits 10/6 to 21/-, mileage extra. No dispensing. Excellent Bungalow residence, in an acre of garden, with fruit trees, tennis court, etc., containing 9 rooms, bathroom, etc. Electric light, h. and c. water. Climate finest in New Zealand. Splendid educational facilities and unlimited sport. Scope for surgery.
14. PARTNERSHIP.—LONDON.—In a populous district, *the half share of* [illegible] dle and working-class Practice, worth over [illegible] *panel of 1,500. Visits 3/6 to 10/6.* Ex[illegible] cessary. House contains professional accom[illegible] *2 bedrooms*, bathroom, etc. Held on lease at rental of about £60 p.a. Premium 2 years' purchase.
15. PARTNERSHIP.—*OUTLYING WESTERN SUBURB.*—A one-third or one-half share is for disposal in a well-established mainly *Utter* working-class *Practice, producing* over £2,300 p.a. *Appointments* worth about £100 p.a., and panel of 1,400. Fees from 2/6 to 21/-. Lowest midwifery *3 gns. Purchaser (if single)* could reside in rooms, or suitable house obtainable. Premium 2 years' purchase.
16. SHEFFIELD.—*Good-class non-panel* non-dispensing PRACTICE in best residential *district. Average* income for last three years over £3,000. Fees 5/- to 21/-. *Midwifery* 3 to 10 gns.; about 30 cases yearly. Surgery premises can be rented on lease, and contain consulting room, *waiting room*, 3 *bedrooms. Electric light.* Garden. Purchaser can choose his own place of residence. Premium 1½ years' purchase, with 1 or 2 *years' partnership introduction* as required.
17. STAFFS.—*LARGE TOWN.*—Owing to ill health of present Incumbent, *an old-established good-class non-panel non-dispensing* PRACTICE is for immediate disposal. Income last year over £1,200. Fees 5/- to *10/-. Commodious* house, in best *residential road.* Price for freehold £1,600, part on mortgage. Prem. £1,500, *payable easy instalments.*
18. *SOUTH-WEST OF ENGLAND.*—Large Thriving Hospital Town.—PARTNERSHIP.—The half or five-ninths share in *an old established better and middle-class* non-panel general and surgical Practice can be acquired by a suitable gentleman possessing the F.R.C.S. degree. *Receipts for the* past three years average over £5,000 p.a. Good house, *with ample accommodation*, at present held on lease with option to purchase. *Premium* 2 years' purchase.
19. SOUTH-WESTERN COUNTY.—LARGE SEAPORT TOWN.—Old-established mixed-class PRACTICE averaging *over £3,000 p.a., including* panel of 2,100. Visits 3/6 to 10/6; *midwifery (discouraged of late)* 3 gns. upwards, about 30 *cases yearly.* Expenses light (Assistant not necessary). House contains *professional accommodation*, 3 sitting, 6 bedrooms, bathroom, etc. Large garden, garage. Vendor's freehold price £2,800, of which £1,200 can remain on mortgage, or might be rented at £96 p.a. Premium 1½ years' purchase, £3,000 down and balance by arrangement.
20. BORDERS OF NORFOLK AND SUFFOLK. — Very *old-estab. good* middle-class PRACTICE, averaging over £1,000 p.a., including panel of 530. Visits from 3/6. Easily worked. Very attractive house, modernized, and containing 3 reception, 6 bedrooms, bathroom (h. and c.), separate professional accommodation. Price for freehold £2,000. Premium £1,500.
21. BORDERS OF CORNWALL AND DEVON.—PARTNERSHIP.—A half share is offered in a very sound mixed-class Practice, situated in delightful district, near coast. Gross cash receipts upwards of £2,900, including panel of over 1,200, and good appts. Low expenses. Convenient house, with 3 reception, 4 bedrooms, and usual offices. Garden. Price £750, part on mortgage. *Premium 2 years' purchase.*
22. DEATH VACANCY.—NORTH DEVON. — UNOPPOSED COUNTRY PRACTICE in delightful district. Very *old-established mixed general* Practice held by the late Incumbent for the past 16 years. Income for 1928 £1,266, including panel of *approximately 700. Exceptionally* good house, standing in *2 acres of garden*, with 2 *reception*, 6 bedrooms, etc., surgery and *waiting room. Electric light. Garage* for two cars. Can be purchased, or might be rented. Premium 1½ years' purchase, or near offer.
23. LIVERPOOL.—Increasing middle and working-class PRACTICE, producing for immediate past 12 *months* £565, including panel of over 700. Visits 2/6 to 5/-. Small convenient house, with 4 bedrooms, etc. Price for freehold £750, most of which could remain on mortgage. Premium 1½ years' purchase.
24. LONDON, S.W.—Pleasant Suburb.—Old-established PRACTICE, producing over £500 p.a., including panel of 417. Visits 3/6 to 5/. *Little midwifery.* Eight-roomed *house, with fair-sized garden. Rent* £60. Premium £500.
25. WITHIN ONE HOUR OF LONDON (good train service).—Old established mixed-class PRACTICE, offering good scope. Average income about £600. Fees 2/6 to 7/6. *Not much midwifery. Easily worked.* Semi-detached house in good condition, with 2 reception, 5 bedrooms, etc. Surgery and waiting room. Garden. Rent on lease £65 p.a. Premium 1½ years' purchase, or near offer.
26. GLOUCESTERSHIRE. — Very old-established unopposed Country PRACTICE, held by Vendor for the past ten years, and situated in attractive district, near good town. Cash receipts for 1928, £[illegible] *and this year at the rate of* £700. Panel of over 500. Fees 2/6 to 12/6. Commodious house, with 6 bedrooms, etc. One acre of garden *and paddock.* Price for freehold £1,200. Premium £900.
27. CHANNEL ISLANDS.—Old-established general PRACTICE. Present *income approximately* £700, but large scope. Advice and medicine 3/6 to 10/6, visits and medicine 5/- to 15/-. Midwifery fees. Commodious house, with 2 reception, 6 bedrooms, etc. Vendor's freehold. Good schools. Price for practice and house £3,000.

Full Schedule of Terms and Conditions will be forwarded on application.

CLEAN UP

THE INTESTINAL TRACT

TOXÆMIA

IS AN IMPORTANT FEATURE
IN A WIDE VARIETY OF CASES.

HEADACHE–INSOMNIA–DEPRESSION

CHRONIC AUTO-INTOXICATION plays an important part in many common complaints. Toxæmia of intestinal origin is the basic difficulty in most cases of the type mentioned above. Laboratory examination of the fæces generally shows an abnormal number of B. coli, staphylococcus, putrificus and streptococcus.

The B. Acidophilus, always present in the healthy bowel, will be found to be very few or almost entirely absent. The reimplantation of B. Acidophilus by oral administration transforms the intestinal flora; overcomes intestinal putrefaction; re-establishes adequate normal defæcation, with the resultant disappearance of the unpleasant symptoms. The most economical and efficient form of acidophilus therapy is

B. ACIDOPHILUS EMULSION

which overcomes toxæmia of intestinal origin and promotes normal adequate defæcation.

For Hypodermic and Intramuscular Injection: 'HYPOLOID' 'ERNUTIN,' in boxes of six hermetically-sealed containers of 0·6 c.c. (approx. min. 10) of Sterile Solution, at 3/4 per box.

A Reliable Ergot Preparation for Hypodermic and Oral Administration

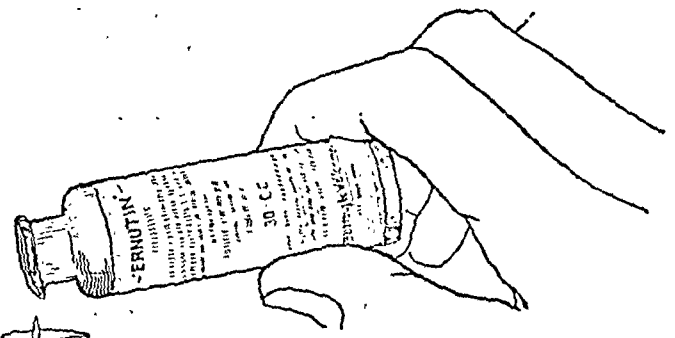
The activity of an ergot preparation is dependent on the presence of the specific active principle—Ergotoxine.

Ergotoxine was originally isolated as the result of researches carried out at the Wellcome Physiological Research Laboratories in conjunction with investigations conducted in the Experimental Laboratories at the Wellcome Chemical Works.

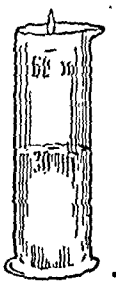
'ERNUTIN' is the practical outcome—a reliable, synthetic ergot.

TRADE 'ERNUTIN' MARK

Produces a sustained contraction of the uterus, assists involution and prevents hæmorrhage



Literature free on request



For Oral Administration: 'ERNUTIN' (Oral), in bottles of 30 c.c., 4 fl. oz. and 16 fl. oz., at 2/6, 7/6 and 25/- each, respectively.

"PITIBULIN"
TRADE MARK

Denotes
Unvarying Pituitary Extract

Conforming to the requirements of the Therapeutic Substances Regulations, 1927, "Pitibulin" is prepared according to the official standards, its activity being now expressed in terms of the accepted unit.

As heretofore, "Pitibulin" maintains the stringently high criteria of therapeutic efficiency, safety in use and stability, self-imposed by its manufacturers—qualities which have given it its high place in the esteem of physicians.

"Pitibulin" is supplied in boxes of 6 and 12 ampoules containing 2.5, 5 or 10 units per ampoule.

Literature giving fuller particulars of the therapeutic application of "Pitibulin" will be sent on request.

KEROL CAPSULES

An Important Notice regarding

Insurance

for Doctors resident in Scotland

and the Counties of Northumberland and Durham.

OWING to the enormous growth and ever increasing pressure of work in the London Offices of the Agency the Committee of Management have decided to establish an office in Edinburgh

as from JUNE 1st, 1929.

It is felt this step will be appreciated by members of the profession residing in the North, and will enable the Agency to deal more expeditiously with enquiries.

MR. R. CHALMERS FERGUSSON has been appointed Agent for Scotland and will welcome all enquiries at the Edinburgh Office of the Agency.

Doctors living in the area covered by the Scottish Office should take this opportunity of considering whether they are at present adequately covered against everyday risks. By reason of its independent position the Agency can give skilled and unbiased advice to Doctors on every class of insurance.

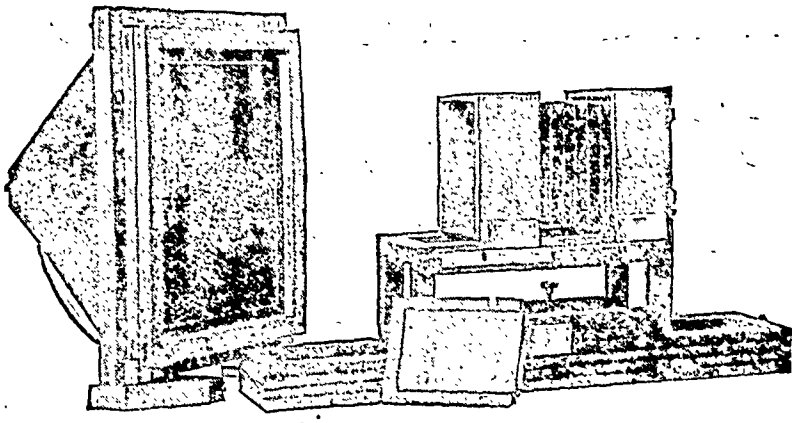
Please Address your enquiries to:

THE MEDICAL INSURANCE AGENCY,

(LIMITED BY GUARANTEE)

B.M.A. HOUSE, 7, Drumsheugh Gardens, EDINBURGH.

"Kodak" X-Ray Reduction Camera



A simple and solidly built camera.

Reduces negatives of any size (up to 17 x 14 ins.)

Suitable for making bromide prints or transparencies of $6\frac{1}{2}$ x $4\frac{3}{4}$ size or smaller and lantern slides.

An automatic focussing scale makes the "Kodak" Reduction Camera exceedingly simple to operate.

Kodak Limited, (Medical Dept.),
Kingsway, London, W.C.2

SIMPLIFIED RADIOGRAPHY

UNTIL recent years the possession of a motor car involved the full time services of a skilled chauffeur. Nowadays a lady in evening dress can drive herself in comfort and arrive at her destination immaculate. SUCH IS THE RESULT OF TECHNICAL ADVANCEMENT AND SIMPLIFICATION.

Within the last decade, improvements in the design and construction of X-ray apparatus have placed Radiography on a similar footing.

With the advent of the "METALIX-PORTABLE" hundreds of medical men have availed themselves of the advantages of X-ray diagnosis.

A bold conception by PHILIPS engineers, the "METALIX-PORTABLE" was designed with a full appreciation of the conditions which obtain in general practice.

Ready in any emergency, at the patient's bedside or in the consulting room, this apparatus can be used with equal facility.

Never before has an outfit with the same outstanding advantages been offered to the profession. The "METALIX-PORTABLE" is not a "condensed" version of a big installation. It is not a large outfit dissembled and packed into a number of small units. *It represents an entirely new principle in design.*

From first to last the "METALIX-PORTABLE" was produced with a definite object in view. For portability it sets its own standard. For efficiency it is truly remarkable. For convenience and safety—unprecedented. Fed from the nearest electric light socket the "METALIX-PORTABLE" can be used by any medical man without previous experience.

Successful radiograms are assured from the start. There is no danger and nothing to go wrong. The special "METALIX" method of construction fully safeguards the operator against unwanted radiation, and electrical shock is impossible. Send a postcard for fully descriptive literature.

FOR small hospitals and ward work, the "METALIX-PORTABLE" is ideal. Every detail has been most carefully planned and its utility proved. The final result can be summed up in one word—PERFORMANCE The outstanding success of the "METALIX-PORTABLE" is testified by medical men the world over. You should investigate its possibilities. Our representative will gladly call and demonstrate without obligation. Send a post card to-day.

NO "VITA" GLASS WINDOW EVER GROWS UNHEALTHY.

In Towns or Country all the year round the ultra-violet rays of daylight can stream unchecked through windows glazed with "Vita" Glass. They continue to do so in perpetuity for "Vita" Glass is permanently health-admitting.

After a short period of exposure to daylight, "Vita" Glass experiences certain chemical changes common to all glass; it becomes "seasoned" and its power of transmitting the ultra-violet rays is thereafter stabilised; and it will not ever depart.

To-day "Vita" Glass is inexpensive. A large window measuring, say, 8ft. by 5ft. can have sheet "Vita" Glass for as little as £4, plus the cost of fixing.

"Vita" Glass was invented by British science and is the only glass of its kind produced by British Industry.

Medical Officers and all others interested in National health problems are invited to write for further information and prices from: THE "VITA" GLASS MARKETING BOARD, 9, Aldwych House, London, W.C.2.

"Vita" Glass is obtainable from local Glass Merchants, Plumbers, Glaziers or Builders

health through your windows

V 197

DOCTORS

prescribe "ARDENTE"

because they know it is fitted from a wide range of distinct types—very inconspicuous—devoid of extraneous buzz—true-to-tone for conversation, music, church, theatre, public and school work. They also know that the guaranteed "Ardente" carries a genuine "after-sale-service"

for their *DEAF* patients

Every important Medical Journal in the land has commended Mr. R. H. DENT'S world-famous aid for its efficiency and simplicity, and, if greater proof were required, it lies in the fact that

many DEAF DOCTORS use "ARDENTE"

"ARDENTE" STETHOSCOPE.—Mr. R. H. Dent also makes a stethoscope specially for members of the medical profession suffering from deafness, slight or acute. Many are in use, and excellent results are reported.

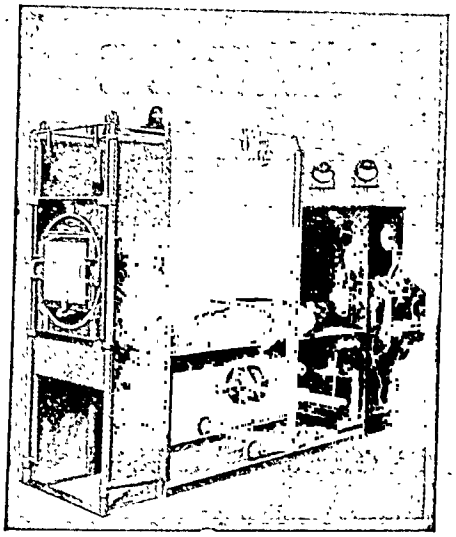
MR R.H.DENT'S ARDENTE FOR DEAF EARS



Now available for every Hospital.

The acme of Simplicity

The NINETY-THIRTY **X-RAY APPARATUS**

Certified by NATIONAL PHYSICAL LABORATORIES as complying with RECOMMENDATIONS OF THE X-RAY COMMITTEE ON PROTECTION.

The power of the apparatus here shown is 90 kilo-volts 30 milliamperes and is therefore capable of meeting the requirements of any hospital for diagnostic radiography and fluoroscopy

The floor space occupied by the complete installation is only 9 ft. × 2 ft. and is therefore suitable for any X-ray room.

The operation of the outfit is so simple that any doctor can obtain radiograms of first-class quality even though he may have had no previous experience. The difficulties associated with X-ray work in the past are now entirely overcome by a device known as the "Automatic Technique Director" which indicates the exact setting of the controls for radiographing any part of the body. The outfit includes a full set of accessories, dark room equipment, etc., and thus COMPRISES A COMPLETE INSTALLATION.

PRICE complete, as illustrated, for use on Alternating Current, including all Accessories **£350**

Ditto, Apparatus for use on Direct Current **£410**

The outfit can be supplied with Metalix X-Ray tube instead of Coolidge X-Ray tube at an additional charge of £10.

Suit the Appliance to the Season.

OCTOBER
NOVEMBER
DECEMBER
JANUARY
FEBRUARY
MARCH

Practically everybody discards heavy underclothing for lighter weight during the summer months, yet patients doing this frequently retain their Winter appliance, being unaware of belts of more porous texture.

The ordinary belt when worn during the Summer induces excessive perspiration, thereby shortening the life of the appliance.

Warmer days call for lighter clothes—why not for more suitable appliances also?

Patients will welcome eagerly the added comfort and complete freedom of movement for outdoor exercises afforded by

Intestinal Debility

"Cristolax" is worthy of careful trial in all cases of constipation. It is composed of 50 per cent. of the purest medicinal paraffin in combination with 50 per cent. of "Wander" Dry Malt Extract. The paraffin content acts mechanically for expelling the fæces, while the high diastatic property of the malt extract assists digestion and improves nutrition.

Where the patient has been accustomed to use an ordinary laxative regularly it is recommended that this should be continued in diminishing doses with the "Cristolax" treatment. It is quickly found that the "Cristolax" method of intestinal lubrication will alone ensure adequate and regular defecation.

Patients highly approve the pleasant flavour of "Cristolax," the complete absence of oiliness and its cleanly form.

For Head Colds Prescribe "Mistol"

MISTOL and the Mistol Dropper are a real advance in nose and throat therapy. Menthol, eucalyptol, camphor, and chlorbutol are combined in a specially prepared petroleum base, which keeps these soothing and healing ingredients in direct contact with the mucous membrane for a considerable length of time.

Unlike douches, Mistol avoids any possibility of sinus trouble. With head tilted back, the patient should let Mistol drop into each nostril until it is felt to be running into the back of the throat. It is manifestly superior to salves which do not reach all parts of the mucous membrane.

Especially efficacious in coughs and colds, simple, congestive, and catarrhal rhinitis, hoarseness, bronchitis, and laryngitis.

Sold in original sealed cartons containing a—

Mellin's Food

PROVES INVALUABLE

in the special dietary of under-weight babies. Its effects are attributable to the high percentage of Malto-dextrin and to its action upon the casein of the cow's milk with which it is mixed for use.

In cases of fermentative diarrhoea, Mellin's Food is invaluable because the maltose and dextrose are entirely absorbed by the small intestine. They are the carbohydrates for the hand-reared baby, and promotes a steady and healthy increase of weight.

TO MEMBERS OF THE MEDICAL PROFESSION.

The pamphlet "Modified Milk in Infant Feeding" will be forwarded with samples post free upon application to:—

MELLIN'S FOOD Ltd., LONDON, S.E.15

The Medical Profession when prescribing "Liquor Carbonis Detergens" SHOULD ADD THE WORD

Wright's

On receipt of your professional card, a package will be sent containing a sample of each of the following—

Wright's Coal Tar Soap.
Wright's Coal Tar Ointment.
Wright's Lysol.
Wright's Liquor Carbonis Detergens.

Although there is no secrecy as to the composition of Liquor Carbonis Detergens (it is described as "an alcoholic solution of coal tar"), the method of manufacture is unique. Imitations will be found to be produced by simple digestion, usually accompanied by some primitive, perfunctory, and inadequate stirring; whereas, in the case of the genuine product, the intimate contact required, for the complete extraction of all the soluble antiseptic constituents, is attained by a series of complicated processes, invoiving the use of highly specialized machinery.

WRIGHT, LAYMAN & UMNEY LTD., 66, Park Street, Southwark, S.E.1

Disturbances of Menstruation & the Menopause

The close association between the efficient action of the ovaries and the blood calcium index, provides a good reason for the administration of Kalzana in these cases. The chemical composition of Kalzana, calcium-sodium-lactate, is unique, and the special feature of the sodium element is that it raises the blood alkalinity, thereby promoting the retention of the calcium constituent.

Recent clinical notes state:

"I tried Kalzana on a patient who was suffering from anaemia due to disorder of menstruation (Menorrhagia). I obtained the most excellent results with it. The patient regained her original health and the menstrual period was regulated."

"I have now had three patients on Kalzana, all for menorrhagia, and it has benefited all three. One of the three also had acute dysmenorrhoea; this is cured apparently."

Kalzana is dispensed by Chemists in air-tight packets containing 50 and 100 tablets. Free from harmful by-effects and is pleasantly flavoured.

Kalzana

Made by A. WULFING & CO., Amsterdam, Holland.

Supplies for your own dispensing, and for Hospitals, Sanatoria, etc., are available at 15/- per 1,000 tablets. Adequate samples for clinical trials, sent with pleasure, upon request.

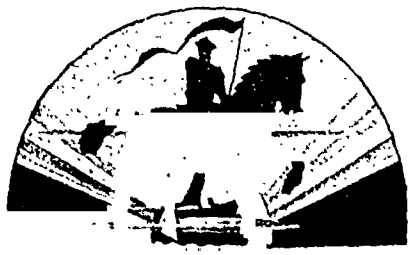
Antibody



Antigens

SEROBACTERINS

Provide forces (antibodies) to battle the invading bacteria of disease while the resistant powers of the body are becoming mobilized.

They also provide a degree of immediate protection to those exposed in time of epidemics.

They reduce the toxicity of the antigen, reducing both local and general reactions, and allowing larger doses to be given.

Thus they save precious time when resistance is lowest and reinforcement vitally needed.

Serobacterins also induce a state of active immunity at least as high as that caused by plain bacterins.

Pituitary
(Posterior Lobe)
Extract
B.D.H.

The importance of standardisation of Pituitary Extracts, emphasised in 1927 when the Therapeutic Substances Regulations came into force, has been appreciated by The British Drug Houses Limited from the time Pituitary (Posterior Lobe) Extract B.D.H. was issued. In fact, when the above-mentioned Act came into force no increase was necessary to bring the activity of Pituitary (Posterior Lobe) Extract B.D.H. into agreement with the official standard.

Every batch of Pituitary (Posterior Lobe) Extract B.D.H. is doubly standardised in regard to:—

Issued also in boxes containing 100 ampoules specially for hospital use

(1) Its action in the contraction of uterine muscle

(2) Its effect upon the blood pressure

Pituitary (Posterior Lobe) Extract B.D.H. is an entirely British product; physicians and surgeons administer it with absolute confidence, realising that it is of guaranteed uniform activity.

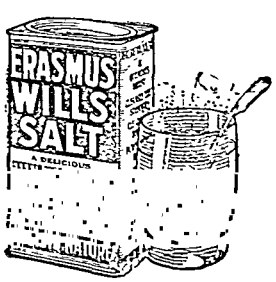
Medicinal Value

HEALTH SALT—do not let your patient be satisfied with an attractive tin or a nice taste. Be sure that the salt is more than a simple effervescing powder. Wills' Salt is a well-balanced combination of saline cathartics, cleansing the digestive tract simply and painlessly.



A full-size trial tin will be sent to any medical practitioner (in the British Isles) on application by postcard.

Note on Infections of the Naso-Pharynx

In these latter days of medicine when people expect the profession to recommend something simple to keep them well rather than take mixtures when they are ill, a preparation which can prevent infection of such an important area as the naso-pharynx should appeal to every practising physician, and especially to Medical Officers who are responsible for the safeguarding of the health of great numbers of children.

The following extract from a recent report speaks for itself with regard to the value of Dimol Snuff—its potency and reliability—in cases of diphtheria carriers, and what has been found a practical solution for the elimination of this troublesome bacillus should be as applicable to the Pneumococcus, Bacillus influenzæ, Meningococcus, Micrococcus catarrhalis, etc.—

> "We are getting very excellent results with Dimol Snuff in the treatment of diphtheria carriers (12 weeks positive cultures) and 'pre-carriers' (6 weeks positive cultures): the latter, of course, with the idea of preventing them reaching the carrier stage.
>
> "Taking both classes together, we consider that we have been successful in about 90% or more cases.
>
> "Most of the failures we find due to some definite chronic nasal disease.
>
> "As a routine we use Dimol Snuff twice a day with an insufflator. If a failure occurs and it is apparently the nose itself and not a question of adenoids then we increase the treatment to six times a day. The children do not appear to suffer any harm from the powder even in these extreme doses.
>
> "The treatment is continued until the child has had negative swabs twice a week for 3 weeks and then another 3 weeks without snuff.
>
> "One more point which is established is that dirty noses are all cleared up, with one exception; in this case I suspect an antrum and shall examine him for such, as he is a big boy." —— —— F.R.C.S.

Children can be taught to take the snuff easily and efficiently in small pinches, or from the back of the hand, and soon learn actually to enjoy the mild warmth induced in their nostrils.

The last paragraph of the quoted Report is testimony which should easily appeal to every Medical Officer.

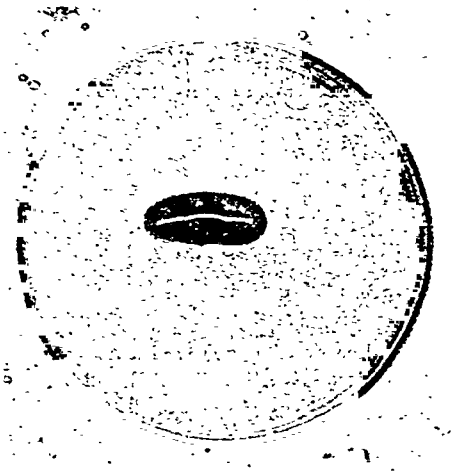
'ULTRATAN'
The LONDON HOSPITAL BINIODIDE CATGUT

(Morley's Process)



"A short length of London Hospital Biniodide Catgut was placed in agar-agar thickly sown with aerobic spores and incubated. The inhibiting action of Biniodide in the catgut not only prevented invasion but exerted a local bactericidal action in the infected agar-agar for a distance of from 5 m.m. to 9 m.m. round the ligature."

Members of the profession are invited to visit the department at the London Hospital, Whitechapel, to inspect the process of manufacture throughout.

A Sample and Descriptive Booklet will be sent post free on application to

ALLEN & HANBURYS LTD.
48 Wigmore Street, London, W 1

The London Hospital Catgut may be obtained from all the leading Surgical Equipment Houses

BOOTS PRODUCTS

Sulphostab (BOOTS)

DIOXYDIAMINOARSENOBENZOL SODIUM FORMALDEHYDE BISULPHITE

Specially prepared for subcutaneous and intramuscular injection in the treatment of syphilis and other spirochætal diseases. Exhaustive clinical trials, both with children and adults, have proved highly satisfactory.

SULPHOSTAB (BOOTS) is practically painless in use, and its high therapeutic activity has been fully demonstrated.

Approved by the Ministry of Health for use in Public Institutions. Manufactured under Licence No. 19 and biologically tested under approved arrangements. Supplied in hermetically-sealed ampoules, in the following doses:—

0·025 gm.	0·10 gm.	0·30 gm.
0·050 gm.	0·15 gm.	0·45 gm.
0·075 gm.	0·20 gm.	0·60 gm.

In single ampoules and in boxes of ten ampoules.

Local Anæsthesia in Surgical Practice

EPITHELIOMA

Typical Case.

W. S. W., aged 41 years.

Diagnosis: Epithelioma of the lower lip.

Operation: Block dissection of neck and excision of growth.

Anæsthesia: Local infiltration and cervical block.

Operation: 120 c.c. of a 0.5 per cent. Novocain-Adrenaline solution was used. Anæsthesia was ideal. Transverse incision was made beneath the ramus of the jaw, with the flap dissected well below the cricoid cartilage, and block dissection upward with "V" shaped excision of the lip followed. This patient waited on himself throughout his convalescence and developed no nausea, vomiting, or thirst.

—Extract from PRACTICAL LOCAL ANÆSTHESIA (Farr).

(Full technique of this and one hundred other operations under Local Anæsthesia will be found in the above work published by Henry Kimpton, 263, High Holborn, London, W.C.1.)

THE SAFEST LOCAL ANÆSTHETIC.

Ample supplies of Novocain are available for the use of Surgeons at all the chief Hospitals. Specify "Novocain" for your next operation.

Does not contain Cocaine, and does not come under the Dangerous Drugs Act.

FAT METABOLISM IN INFANCY

The use of cream as a source of fat in home milk modification is unsatisfactory. The expense, the variable percentage of fat, the frequent contamination, the bad preserving qualities, are grave disadvantages.

In most emulsions, full cognisance has not been taken of the necessity for supplying the infant with a cream possessing properties and characteristics identical with those of normal breast cream. Cod-Liver Oil emulsions with their high iodine number (120) are apt to provoke vomiting.

To meet these requirements the manufacturers of COW & GATE have, after intensive research, produced BRESTOL.

Brestol

BRESTOL closely resembles the fats found in BREAST milk.

BRESTOL.	BREAST MILK.	COMPOSITION.
Saponification. No 206 ...	206.0	Fat 50 per cent.
Iodine No. 50	46.0	Sugar 40 per cent.
Reichert Meisol No. 3.3 ...	2.6	(Mainly dextrose)
Polenake No. 1.7	1.6	

It also contains concentrated orange juice, concentrated seven times, which, if reckoned in terms of the original fresh orange juice, would mean that each teaspoonful of BRESTOL contains half teaspoonful of fresh orange juice.

It is free from all dangerous organisms which are likely to occur in ordinary dairy cream, and keeps indefinitely if stored in a cool, dark place.

The cod-liver oil and orange juice in the preparation of BRESTOL have been biologically tested for vitamins A, C & D.

Its calorie value is 178 per oz. (per teaspoon 22).

It can be recommended for all cases for substituting and superseding Dairy Cream or ordinary Cod-Liver Oil emulsions.

In addition to its value in modification of milk, it will be found indispensable in backward babies, in babies underweight; in Marasmus and Tuberculosis even in older children.

The manufacturers will gladly supply Samples and any further information, if required, and wish to remind Members of the Medical Profession that the Cow & Gate Laboratories are always at their disposal for experimental work in connection with Milk Foods.

VACCINE TREATMENT
OF
GONORRHOEA

In the treatment of Gonorrhoea the use of Vaccines, in conjunction with the usual routine treatment, materially shortens the course of the disease and prevents complications.

DETOXICATED VACCINES are recommended for preference owing to the massive doses which may be administered with little or no reaction, at the same time achieving great immunity, but where price is a consideration "Ordinary" Vaccines are available at very low prices.

For all early cases of Gonorrhoea, also in cases of Gonococcal Arthritis, Orchitis, Iritis, etc., Gonococcal Vaccine "A" is indicated. This is a pure Gonococcal Vaccine prepared from many strains (Polyvalent).

In cases of more than three or four weeks duration Gonococcal Vaccine "B" is recommended. This Vaccine is composed of equal parts of the above Vaccine "A" and the organisms found as secondary invaders in chronic cases.

Practitioners desiring additional information regarding the above Vaccines and also the special Gonococcal Products for Diagnosis and Test of Cure are invited to write to:

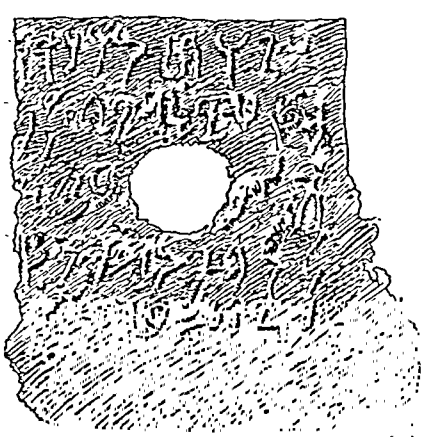
INSCRIPTION IN KHAROSHTHI, THE SCRIPT USED IN COMMUNICATIONS BETWEEN NORTH-WEST INDIA AND THE FIRST PERSIAN EMPIRE.—



Kharoshthi was employed in North-West India as being better known there than was the Brahmi used throughout the rest of the Empire. It seems to have been adapted from the Aramaic form of script which prevailed generally in Western Asia in the 5th century B.C. It is a Semitic script and is considered to have come originally from the same source as the Brahmi. Kharoshthi was employed also in Chinese Turkestan, where the official language was a dialect imported from North-West India. It had long been thought to have died out in India in the 3rd century A.D., but recent discoveries prove that it was still in existence at least as late as the middle of the 5th century of our era.

Toast *and* Toast Racks superseded

The "RYVITA RACK" has displaced the old-time toast rack

Every day, more and more people are discovering how much more delicious, how much better than toast is "Ryvita Crispbread," the wonderful daily bread of Sweden.

"Ryvita" is made of rye—and nothing but rye—the only cereal from which this the true Crispbread can be made. The first people in this country to eat it were those most highly qualified to judge food values—doctors, dentists, and dietetic experts. "Ryvita" reached the multitude by way of the specialist, thus—despite envious imitators—establishing here "The Ryvita Crispbread Habit."

Eaten as your Daily Bread—"Ryvita," the Veritable Bread of Life, helps to make indigestion, constipation, malnutrition, and obesity unknown. Yet . . . so unique is this wonderful bread, that it is practically impossible, even when dieting, to eat too much of it.

Try "Ryvita" with butter and marmalade. Notice how it sustains without cloying . . . how it gives you an exhilarating sensation of well-being and clear-headedness . . . how you work better, play better, and feel better, on "Ryvita."

You will then understand why the old toast rack is now the "Ryvita" rack.

Send a postcard for generous FREE Sample to the Ryvita Company, 415, Ryvita House, 96, Southwark Street, London, S.E.1. Sold by all good grocers and stores at 1/6 per (40-50 slice) 1-lb. carton; ½-lb., 1od.

Makes you fit—

RYVITA CRISPBREAD

keeps you slim

A Lecture ON THE PRINCIPLES OF SPA TREATMENT.

DELIVERED BEFORE THE DUNDEE DIVISION OF THE BRITISH MEDICAL ASSOCIATION

BY

WILFRID EDGECOMBE, M.D., F.R.C.P., F.R.C.S.,

CONSULTING PHYSICIAN TO THE HARROGATE INFIRMARY.

THE use of natural mineral waters and baths in the treatment of disease is of great antiquity, dating back to Greco-Roman times, or even earlier. Founded originally on pure empiricism it has gradually emerged on to a higher plane by reason of the scientific work that has been done on the subject, mainly during the last century, and it may now be said to rest on a more or less scientific basis. In spite of this there lingers in the mind of the medical profession at large a mild suspicion as to the real utility of spa treatment, though the laity are well persuaded of its value. Perhaps the main reason for this distrust lies in the advertising of spas by the lay managements, for in Great Britain all the spas are under municipal or private control. Abroad many of the spas are under State control, and advertisement of them proceeds on similar though usually more intensive lines. The claims made by most spas are apt to be extravagant. Lay advertisement, on commercial lines, of the general amenities of a spa, is permissible, but the advertising of the purely medical aspects needs revision, and should be rigidly controlled by the medical profession, and no statements should be put forward that cannot be abundantly justified on clinical or experimental grounds.

Spa treatment may be regarded from two widely different angles: that of the general practitioner or the consulting physician who is desirous of, or in the habit of, sending his patients for treatment to a spa; and that of the practitioner on the spot to whose care the patient is committed. Each views the subject in a different way. The general practitioner, at the outset of his career, is frankly ignorant of spa treatment, what it can do, the principles underlying it, and the types of diseases likely to be benefited thereby. This is not surprising, for in his crowded curriculum there is no room for any instruction on the subject. Older practitioners who have some acquaintance with spa treatment include, first, those who accept the valuation put upon the spas by interested parties and are content to send their patients in the hope of relief or cure without troubling to inquire for themselves the rationale, if any, underlying the treatments; secondly, those of more inquiring mind who are rightly sceptical and desire to know the scientific grounds, experimental or clinical, on which the claims for the efficacy of spa treatment are based; and, thirdly, those, in the minority, who have made such inquiries and are satisfied that there is adequate reason for the faith that is in them. It is to the first two groups that my statement of principles is directed.

The outlook from the standpoint of the spa-physician varies according to the type of individual. There are those of the ultra-rational school who have an abounding faith in the curative properties of mineral waters and baths in general, and of the water and baths of their own resort in particular; claiming that they have special virtues inherent in them that are not capable of mensuration by the methods of science, and that experimental work has not succeeded, and cannot succeed, in elucidating these intangible properties. When asked to furnish evidence of their faith they point to clinical results, claiming that a mode of treatment that has stood the test of centuries cannot be devoid of foundation, whether rational or ultra-rational. And there is something to be said from their point of view. On the other hand, there are those of the rational school, who maintain that the admittedly good results often achieved by spa treatment are explicable on rational grounds; that the waters are to be regarded as compound drugs whose pharmacological action can be ascertained by experimental methods; that spa treatment rarely consists solely in the administration of waters—other factors, baths, exercise, diet, climate, etc., coming into play; and that the effects are obtained by the application of certain general principles of treatment that are followed in greater or less degree at all spas.

THE ESSENTIALS OF SPA TREATMENT.

At the outset it is necessary to define what is meant by a spa. By a spa is understood a health resort having, as its leading feature, a natural mineral water, or waters, of a distinctive type. Spa treatment connotes the interplay of many factors. It embraces the use, singly or combined, of many agents, physical and psychical.

The physical agents comprise: (*a*) natural mineral waters, used internally by drinking, and externally as baths; (*b*) special baths and douches of various kinds—massage douches and needle douches, etc.; (*c*) accessory physical methods, such as massage, exercise, mechano-therapeutics, inhalations, and various electrical procedures; and (*d*) climate, diet, and general regimen. The psychical factors include: (*a*) change of scene and environment; (*b*) absence from business worries; and (*c*) recreation and general amenities. It is not only the taking of this or that water, or the use of any special bath, but the summation of the whole that constitutes spa treatment.

MINERAL WATERS OF BRITISH SPAS.

The chief British spas are, in alphabetical order, Bath, Buxton, Cheltenham, Droitwich, Harrogate, Leamington, Llandrindod, Strathpeffer, Trefriw, and Woodhall Spa; which together comprise the British Spa Federation. To these may be added certain lesser-known resorts: Llangammarch, Llanwrtyd, Moffat, Bridge of Allan, Tunbridge Wells, Matlock Bath, and others. The chief types of mineral waters occurring in Great Britain are as follows:

1. *Simple thermal waters*, issuing hot, of low mineral content, and radioactive in varying degree. They contain a relative excess of calcium salts, and little sodium chloride. They are exemplified by the waters of Bath, Buxton, and Matlock Bath. Their action is mainly diuretic, and changes are excited in nitrogenous metabolism, as evidenced by alterations in the urinary output. It is claimed that the radioactivity of the water is largely responsible for its effect, but this is as yet unproved.

2. *Saline waters*, issuing cold, highly mineralized, and having little or no radioactivity. They are subdivided into three groups:

> (*a*) *Muriated*, containing sodium chloride in large amount. For example, the waters of Droitwich, which contain 31 per cent., or ten times as much as sea water, and those of Nantwich and Northwich. They are only used externally for bathing purposes, and are heated by steam. A milder saline water, used internally, is found at Llangammarch.
>
> (*b*) *Muriated sulphated*, containing, in addition to sodium chloride, the sulphates of sodium and magnesium. Such are the waters of Cheltenham, Leamington, and Bridge of Allan. They have an aperient action on the bowel, and are also diuretic.
>
> (*c*) *Muriated alkaline*, containing sodium bicarbonate in relative excess, in addition to sodium chloride. The only example of this water in Great Britain is the Pittville Spring at Cheltenham.

3. *Sulphur waters*, issuing cold, highly mineralized, and radioactive in low degree. They are subdivided into two groups:

> (*a*) *Saline sulphur*, containing sodium chloride in excess, with many other salines, and sulphur in the form of sulphides and sulphuretted hydrogen gas. Examples are found at Harrogate, which has a great range of saline-sulphur waters, strong and mild: at Strathpeffer, in whose waters the sulphuretted hydrogen is in relatively large amount: at Llandrindod, where the waters belong to the mild saline-sulphur class; and at Llanwrtyd and Moffat. The action of the stronger members of the group is aperient on the bowel and stimulating to the liver, while the milder members act mainly on the kidneys. Both provoke changes in metabolism.
>
> (*b*) *Alkaline sulphur*, containing carbonates in addition to chlorides and sulphides. Examples of these occur at Harrogate, where they are chiefly used for bathing purposes in skin cases.

4. *Chalybeate waters*, issuing cold and containing iron in addition to salines in various amounts. They are subdivided into two groups:

(*a*) *Saline iron*, containing sodium chloride and other salines, with iron as carbonate, chloride, or protosulphate.

(*b*) *Pure chalybeate*, containing iron as their chief constituent, with minimal quantities of other substances. Examples are found at many spas—Buxton, Harrogate, Llandrindod, Strathpeffer, Trefriw, Llanwrtyd, and Tunbridge Wells.

5. *Bromo-iodine waters*, issuing cold, containing small amounts of bromine and iodine, in addition to other salines such as sodium chloride, *calcium, and magnesium*. The only example in Great Britain is the water of Woodhall Spa.

Pharmacological Action of Spa Waters.

In considering the pharmacological action of these waters it must be borne in mind that they are not single drugs, but complex solutions of multiple chemical substances in a state of ionic dissociation, and in many instances in a colloidal form. To attribute the action of a water to any one constituent is fallacious; each must be regarded as a compound drug and its pharmacological action assessed as the resultant effect of the whole contents. Large clinical experience has made us familiar with the broad effects of these waters, and more recently experimental work undertaken from time to time at certain of the spas has explained these effects and furnished for them a scientific rationale.

The general effects of mineral waters, as contrasted with the effect of an equivalent quantity of plain water, are (1) the stimulation of metabolism, giving rise to increased oxidation, diminished formation, and increased elimination, of waste products; (2) the antiseptic action of the sulphur group; (3) the action on the thyroid of the iodine group. There is no evidence that any of these waters have a truly specific effect in any disease—specific in the sense that quinine is a specific for malaria, emetine for amoebic dysentery, or the heavy metals, mercury and bismuth, for syphilis. Some waters act mainly on the kidneys, some on the bowels, some on the liver, in an analogous way to other drugs, simple or compound, but no true specificity has been shown to exist.

Baths and Accessory Treatments.

The next factor in spa treatment is the use of baths. These may be divided into baths particular to each spa, and those common to all.

The particular baths are the natural mineral water baths of each place given as immersion baths or swimming baths —for example, the sulphur baths of Harrogate, the immersion baths of Buxton and Bath, the saline bath of Droitwich. Here again there is no convincing evidence of any specific action. The effects are due to: (*a*) temperature and its influence on the circulation and the nervous system; (*b*) the hydrostatic effect of the weight of the water pressing on the body; (*c*) the stimulation of the nerve endings of the skin by the salines in solution, and the resultant reflex effect on the vessels; (*d*) the inhalation of radium emanation, when present, or of carbon dioxide, as in the aerated baths.

The baths common to most spas are: (*a*) the massage douches—Aix, Vichy, and trough massage; (*b*) douches without massage—local douches, needle douches, Scotch douches, sitz douches.

Various special baths are peat, brine, Nauheim, hot air, radiant heat, vapour, Turkish, whirlpool, paraffin wax, liver packs, local packs of peat or fango mud.

The physiological effects of these baths have in most cases been well worked out. The fundamental action of them all is the excitation of changes in the circulation, general or local, leading to improved blood and lymph supply to the tissues, and accelerated interchange of tissue fluid; the raising of the resistance of the body to infection by the production of bactericidal substances in the blood, and the flooding of local parts with fresh blood and lymph charged with antibodies; and the effects, sedative or stimulant, of temperature, percussion, massage, etc., on the nervous

Accessory treatments include intestinal lavage on the Plombières system, a mineral water more or less isotonic with the blood being used; massage in its different forms; mechano-therapeutics; and electrical treatment by means of high-frequency, faradic, galvanic, and static currents. On the other factors—climate, diet, change of environment etc.—it is not necessary to lay stress.

Claims Made for Spa Treatment.

When we come to consider the claims made by the various spas, British, French, and other European, of their efficacy in the treatment of disease, and to examine critically the lists of diseases it is desired should be sent to them, we are at once struck by the extraordinary resemblance of these lists to each other. I have tabulated lists of the diseases claimed to be treated at the British spas taken from the *Handbook of the British Spa Federation* of the chief French spas taken from the *Spas of France issued by the Medical Commission of the Thermal Resorts of France*; and the Middle European spas, taken from the *Bade-Almanack*. Examples of each group may be quoted and contrasted. In the British group, Buxton and Harrogate have very dissimilar waters. Here is Buxton's list of diseases:

Gout; gravel; rheumatism; fibrositis; sciatica; neuritis; rheumatoid arthritis; osteo-arthritis; high arterial tension; arterio sclerosis; cardiac affections; skin diseases; colitis; anaemia.

Here is Harrogate's list:

Gout and other metabolic disorders, glycosuria, obesity. Functional liver derangement, and early cases of cirrhosis, cholelithiasis and cholecystitis. Chronic skin diseases. Synovitis, fibrositis sciatica, and other forms of neuritis. Arthritis—rheumatoid chronic rheumatic, and toxaemic varieties. Mucous colitis, chronic dysentery, constipation, and intestinal toxaemias. Anaemia in its various forms. Nervous diseases, neurasthenia, and hysteria Hyperpiesia. Sequelae of tropical diseases.

You will note the very close resemblance between the two. Much the same is true of the other British spas.

In the French group, Aix and Contrexéville have waters presenting striking differences between them. Aix claims to treat the following:

Chronic rheumatism—articular, muscular, neuralgic. Articular gout, polyarthritis deformans, and osteo-arthritis. Sciatica neuritis; syphilis; dermatoses, etc.

The list for Contrexéville is as follows:

Nephritis; gravel; urinary disorders; gout; hepatic disorder diabetes; arterial hypertonus and early sclerosis; arthritic disorders.

It is true that there are certain other spas in France notably La Bourboule, Mont d'Or, and Bagnoles de l'Orn whose claims are narrowed to limited groups of disease but these are the exception. I will cite one further list this time from Marienbad, in the Mid-European group:

Disorders of metabolism—obesity, gout, diabetes. Anaemia Disease of the digestive organs—stomach, bowel, and liver Diseases of the respiratory and circulatory organs—pulmonary catarrh, fatty heart, arterio-sclerosis. Affections of the urinary organs; of the female genital organs; of the nervous and locomotor systems. Sciatica, peripheral neuritis, chronic rheumatism

Now either one of two conclusions may be drawn from these facts: there is no escape. Either the claims made are extravagant and cannot entirely be substantiated, in which case they stand urgently in need of revision; or they are in the main true, in which case it must follow that there is nothing truly specific in spa treatment in general.

It is absurd to suppose that such diverse waters as those of Buxton and Harrogate, Aix and Contrexéville, can be equally specific for the average case of gout, or for the group of chronic rheumatic diseases which they all claim to treat; and similarly through the list of diseases. If we attempt to formulate clear and precise indications as to which case of gout, arthritis, rheumatism, colitis, or any other disease should be sent to which spa, great difficulty is encountered. These indications can only be stated in a general, somewhat nebulous, way; no definite rules can be laid down owing to the absence of specific data to serve as a basis, for the claims founded on clinical experience also are apt to be too vague and too wide. If, on the other hand, we grant that the claims made are in the main justified, we are driven to the conclusion that spa treatment, if it be beneficial in the variety of diseases for which

its value is claimed, must be so by reason of certain broad general principles on which it is founded.

It will be noted first that the diseases enumerated in the lists belong to the chronic order; secondly, that the diseases are mainly of the chronic metabolic or nutritional type, the chronic diathetic disorders, and the chronic infections. Now chronic nutritional disease may be brought about by prolonged disturbance of one or all of the three stages of the process of nutrition, which are sequentially dependent each on the other. The primary or alimentary stage is governed by the character of the food ingested, and the capability of the digestive organs. The intermediate stage of storage depends on the functional activity of the liver and its power of destroying toxins. The third, or distributive stage, depends on the proper interchange of fluid between the tissues and tissue fluid, and between the latter and the blood; and this in turn depends largely on the soundness of the blood vessels and on their capability of contraction and dilatation—in other words, it depends largely on the changes in blood pressure. The first two stages may be studied clinically by various means; the performance of the last stage cannot be directly observed, but may be inferred from the changes that take place in the capillary circulation as deduced from observation of the arterial and venous blood pressure.

Aims of Spa Treatment.

In spa treatment the main factors consist of the administration of waters, of baths, appropriate dieting, and exercise, active or passive. Three of these influence the body primarily by changes induced in the circulation: (1) waters, largely by their diluent effect on the blood, apart from the action of their medicinal constituents on various organs, and the metabolic changes they excite; (2) baths, entirely by the changes they excite in the circulation and the nervous system, for there is no proof that mineral constituents of waters used for bathing are absorbed by the skin; and (3) exercise, by stimulating the circulation and promoting the flow of lymph. Diet, though it mainly concerns the primary or alimentary stage of nutrition, has a marked effect on the blood pressure, and through the blood pressure it influences the final or distributive stage.

In chronic infective disease the first step is to locate and remove, if possible, the source of infection; secondly, to build up the natural resistance of the body to infection; and thirdly, to attack the local residual conditions resulting from infection—for example, arthritis—by balneological and other measures, to improve the local blood and lymph supply.

I would state the broad principles as follows: the aim of spa treatment is to regulate faulty tissue interchange, rendered abnormal by excessive or defective intake, by defective or excessive output, by lack of exercise and fresh air, or by the action of poisons, chemical or bacterial. Improvement of interchange between blood and body fluids leads to improved metabolism, increased resistance to disease, and increased power of recovery. The modes of effecting these aims are:

1. The securing of increased elimination of waste products through the bowel, by means of waters having an aperient action; through the kidneys by waters having a proved diuretic effect; and through the skin by means of baths having a diaphoretic action.

2. Improvement in the circulation and acceleration of the flow of tissue lymph, thereby enhancing the rate of dislodgement of waste products from the tissues and the supply of fresh nutriment from the blood. Such quickened metabolic changes are brought about by mineral water baths, massage douches, and other bathing procedures.

3. Through the resulting changes in general metabolism, securing increased resistance to disease and increased power of recovery. Recent research tends to show that the bactericidal power of the blood may be raised by radiant light and heat baths, by ultra-violet rays, and by procedures such as the liver pack, that cause a powerful stimulation and reddening of the skin.

4. The regulation of the intake of food according to the needs of the particular case.

5. The regulation of the amount of exercise or rest.

6. The securing of conditions having a psychological effect, such as change of scene and surroundings, absence from work and worry, and suitable congenial occupation or recreation.

7. Lastly, the removal, where possible, of the cause of the disease—for example, the removal of any discoverable source of local infection.

Types of Spa Treatment.

On these principles, then, there are three broad types of treatment applicable to the various chronic diseases:

1. The anabolic type, where the aim is to build up a deficient metabolism by increasing the intake, by promoting assimilation, and by avoiding the production of excessive output. Examples of cases suitable for this type of treatment will readily suggest themselves: (*a*) convalescence from acute diseases; (*b*) anaemia and general debility; (*c*) post-tropical conditions; (*d*) functional nerve disorders; (*e*) chronic infective diseases such as rheumatoid arthritis.

2. The metabolic type of treatment for cases in which metabolism is not necessarily deficient or excessive, but is defective and faulty and requires "alterative" treatment. Such are: (*a*) the gouty; (*b*) the worn-out and jaded from overwork and lack of exercise; (*c*) the hyperpietic; (*d*) the functional disorders of the liver; and (*e*) a large proportion of the chronic rheumatics and fibrositics.

3. The katabolic type of treatment, where the aim is to promote over-stimulation of the metabolic processes, and allow tissue waste to overbalance tissue regeneration, as in the obese, the overfed, and the under-exercised.

Most of the diseases scheduled in the various lists quoted above will be found fundamentally to fall into one or other of these three groups, and to be amenable to treatment on the principles I have laid down for each. These principles may be carried out equally well at most spas in possession of the necessary equipment. Naturally, spas will differ in their modes of application of the principles—one having waters more suitable for eliminant action by the kidneys; another, waters which act on the bowel; another, waters which have a proved action on the liver, and so on. Also the factors of climate, geographical situation, and time of year must be considered in the choice of a spa. But the principles remain the same, and are acted upon in so far as the resources of a given spa permit.

General Conclusions.

My argument leads me to this conclusion: that in the present unsettled state of our knowledge of the precise action of mineral waters and baths, physicians who practise at spas should lay no claims to the successful treatment of chronic disease by the specific action of these agents, but should rather stress the fact that they claim to treat these diseases on broad general principles; that they act as general physicians, making use largely of physical methods, in addition to ordinary therapeutic treatment, rather than as purely spa physicians, putting their faith in the specific action—as yet unproved—of any particular water or bath.

Far be it from me to say that natural mineral waters have no action beyond that of mere diluents. Many of them—notably the strong sulphur water of Harrogate—are potent drugs whose pharmacological action has been well ascertained. My point is that none of them has been proved to be a truly specific remedy in any specific disorder—as, for example, gout, rheumatoid arthritis, or chronic rheumatism. It may be said that my conclusion shakes the foundation on which the edifice of spa treatment is supposed by many to rest. On the contrary, I am seeking to replace insecure foundations, constructed of unproved material, by others of a more durable character.

That spa treatment has a real utility in the management, both preventive and curative, of chronic disorders I am fully convinced. The important thing is to get the cases early enough while the disease is still incipient and amenable to cure or arrest. Too often they are sent in a hopeless condition—for example, advanced cases of arthritis—when miracles are expected and disappointment inevitably ensues, to patient, to physician, and to spa practitioner.

VITAMIN A AS AN ANTI-INFECTIVE AGENT.

ITS USE IN THE TREATMENT OF PUERPERAL SEPTICAEMIA.

BY

E. MELLANBY, M.D., F.R.C.P., F.R.S.,

AND

H. N. GREEN, M.D., CH.B., M.Sc.

(From the Pharmacology Department, University of Sheffield.)

(Preliminary Communication.)

LAST year we published an account of an experimental investigation on animals, which suggested that an important function of vitamin A was to raise the resistance—either local or general, or both—to bacterial infection.[1] Animals deprived only of this vitamin died ultimately with multiple foci of infection, whereas control animals receiving vitamin A remained in good health, free from infection. Animals which had developed infective lesions, if given in time abundant vitamin A, usually recovered completely. In the publication referred to we dealt with the work of other investigators on the subject, and this will not be repeated here. Reference may, however, be made to one fact which has been described since that date. A discussion has ranged round the question of whether in animals deprived of vitamin A the epithelial hyperplasia precedes the local infection in the same position or vice versa. Tyson and Smith have found histological evidence of infection preceding the epithelial changes in the tongue and kidney.[2]

THE BASIS OF THE INVESTIGATION.

The results of our animal experiments seemed to be sufficiently impressive to warrant an investigation to determine whether vitamin A had any specific action in human infection. Some general clinical evidence in various types of infection, and particularly in pneumonia, lent support to the idea that preparations rich in vitamin A had a definite effect in increasing the general resistance and in promoting recovery, but we were met with the usual difficulty in clinical work of assessing the value of the remedy in diseases which often have a low mortality rate whatever the treatment given.

In the publication referred to above we suggested specially that a deficiency of vitamin A in the body might play an important part in the etiology of puerperal sepsis. It is generally recognized that many sections of the community, and, indeed, many individuals of all classes, receive an allowance of fat-soluble vitamins in their diet well below the optimal. The pregnant woman is in still greater danger of a deficiency of this nature, for she has not only to supply her own body but also that of a rapidly growing organism. The growing animal, whose metabolic rate is relatively much greater than that of the adult, is known to make greater demands on its stores and supplies of vitamin A than is the slow-growing or adult animal. It is probable, therefore, that, unless her intake of vitamin A is high, the liver stores of the substance in a woman are gradually diminished during pregnancy, so that, if vitamin A plays the part in raising the resistance to infection indicated by the animal experimental results, she might be expected to be more susceptible to sepsis at this time. A somewhat analogous phenomenon is seen in the increased dental caries experienced by women during pregnancy, due most probably to the sacrifice of vitamin D, the calcifying vitamin, to the developing foetus. In any case, it was obviously possible to test this hypothesis of the relationship of puerperal sepsis to a deficiency of vitamin A. We are at present engaged upon such a test at the Jessop Hospital, Sheffield, with the assistance of the registrar, Miss Pindar. Out-patients attending the hospital in the prenatal period are being given a supply of a preparation rich in vitamin A two weeks prior to and one week after confinement, and the regards the development of sepsis with those in an equal number of patients not receiving this addition. It is obvious that work of this type must involve large numbers of patients, and at the present time the numbers are not sufficiently large to warrant publication, although it may be stated that the results obtained are definitely in favour of the hypothesis that vitamin A has a prophylactic anti-infective action when given under these conditions.

In the meantime we thought we could get evidence on this point more rapidly, and possibly more dramatically, by studying the action of vitamin A in puerperal septicaemia. For if the deficiency of vitamin A in the body is responsible for the lowered resistance to infective organisms seen in puerperal septicaemia, then the exhibition of large doses of the same vitamin to patients suffering from this condition would be expected to have some curative effect. This prophylactic and curative relationship of small and larger doses is seen in the case of vitamin C in scurvy and vitamin D in rickets, and the same would be expected of vitamin A in infective conditions if the hypothesis of its anti-infective function were sound. The choice of puerperal septicaemia, where the blood infection is usually due to a haemolytic streptococcus, had the advantage that the mortality rate is so high that the series of cases in which complete cure is brought about need not be large in order to allow a decision as to whether the remedy tested is having a beneficial effect. In the present communication, which is of a preliminary nature, the number of cases treated only allows the claim that the administration of preparations rich in vitamin A has had some beneficial result. Whether this form of treatment is specific for septicaemia, and possibly bacterial infections in general, can only be decided after the subject has been investigated on a much larger scale.

The Method Adopted.

The treatment consisted, so far as we are concerned, of the administration of preparations containing vitamin A. Two preparations were used, X and Y. In order to give some idea of their content of vitamin A, it may be said that, using the colorimetric method of Carr and Price, preparation X gave a dilution test of 1 in 20,000 to 1 in 30,000, and preparation Y of 1 in 300,000. An average specimen of cod-liver oil will give a corresponding figure of 1 in 2,000, so that X, on the average, was about 15 times and preparation Y about 150 times as rich in vitamin A as cod-liver oil. (It has not yet been definitely proved that the antimony colour reaction is specific for vitamin A, but all evidence tends to show that this is the case.)

When the condition of the patient was such that X could be administered it was usual to give 2 drachms (about 7 c.cm.) twice daily. On the basis of the above colour test figures this is equivalent to about 5 ounces of cod-liver oil. In some cases (vide Cases iv and v later) it was impossible to give X by mouth owing to vomiting, and it was necessary to give preparation Y in doses of 2 minims hourly in a teaspoonful of orange juice for twelve doses daily. When Y was thus given, about 1½ c.cm. was the total daily dose. This is equivalent, on the above reckoning, to 225 c.cm. of cod-liver oil—namely, 8 ounces. In another case, treated before Y was obtainable, the preparation X, since it could not be taken by mouth, was injected subcutaneously in 1-drachm doses for two days. This procedure was not continued, however, for although the injected doses were apparently absorbed fairly rapidly, and gave rise to no local sepsis, we did not think this mode of administration desirable.

It may be well to add that, since the patients were not under our direct charge, the treatment in some cases was not confined to the administration of vitamin A preparations. In one case (Case ii) the patient received quinine, another case (Case v) received a course of intramuscular metarsenobillon. It is difficult to appraise the value of these additional forms of treatment, but in view of the fact that they had been used on similar cases over a number of years at the same hospital with results which cannot be considered good, it is possible that, as curative agents, they are not of great value, and did not influence the course of the disease to any great extent. Except for the

applications, Cases i, iii, and iv received only the vitamin A treatment recorded above.

Preparation X is radiostoleum, kindly supplied for this investigation by British Drug Houses Ltd. Preparation Y, the very potent concentrate of vitamin A, was placed at our disposal by Lever Brothers, Port Sunlight. To both of these firms we wish to express our thanks.

Analysis of Results.

At the Jessop Hospital, Sheffield, and its annexe for septic cases at Norton, the results obtained in puerperal cases of haemolytic streptococcal septicaemia during the past two years are as follows:

	Prior to Vitamin A Treatment.		Vitamin A Treatment.	
	1927.	1928.	1929 (3 months).	
Number of cases... ...	8	16	5	
Number of recoveries ...	2	0	5	

Of the 24 cases not receiving the vitamin A treatment, 22 died, giving a mortality of 92 per cent. In the 5 cases receiving vitamin A there were no deaths, and all made a complete recovery.

Reference to the case notes given below will show how the different cases responded to the treatment. It would appear that the effect of vitamin A is rather to increase gradually the general resistance than to act suddenly, as might be expected in the case of a substance having a specific bactericidal or antitoxic effect. It will be noted that blood cultures in all cases became sterile, and although the number of cultures made in each case were too few to allow the determination of the exact time required for this development, it was usually found that about a fortnight after the beginning of administration of vitamin A no organisms could be grown from the blood. Nothing immediate and dramatic in the effect of this form of treatment has been noticed. It may be added that we have also treated a number of other cases of severe puerperal sepsis by the same means, but since their blood cultures were negative we have not considered them in this publication. Of all these cases the only failures were two of severe peritonitis.

CASE I.

The patient, a primipara aged 30, was delivered at her own home by means of forceps on January 6th, 1929. Two days later she had a temperature of 100° F., and, on January 12th, perineal sutures were removed owing to sepsis. On the 13th she was admitted to hospital with a history of delirium.

On admission she was pale and had an anxious expression; the temperature was 100.6° F., pulse rate 126, respiration rate 26. The edges of a large perineal tear, extending almost to the sphincter, were sloughing. On January 15th she had tenderness and rigidity on the left side of the abdomen, and swabs from the perineum and cervix showed pus and Gram-positive diplococci. On the 17th her temperature was 101.6° F., pulse rate 120, and on the following day she received the first of a series of intrauterine injections of glycerin and glauramine.

On the 21st her temperature was 102.4° F., pulse rate 120, and the administration of preparation X by mouth, in 2-drachm doses twice daily, was started. In a blood culture made on the 22nd *Streptococcus haemolyticus* was grown in twenty-four hours; on the other hand, the perineum was much cleaner and the abdomen less tender. On the 23rd the temperature was 104° F., and the pulse rate 122. On the 24th she had pain and tenderness in the right loin, but the perineum was healing. Fever continued on the 25th, the temperature being 102° F., the pulse rate 124; but on the 28th the temperature subsided slightly and the abdomen felt less tender. On the 30th and on February 1st the temperature was 100° F., and the pulse rate about 120; tenderness developed in the gall-bladder region. On February 6th the temperature was down to 99° F., though the pulse rate remained at 120; she was tender in the left iliac fossa, but less tender over the gall-bladder.

From this time on the temperature and the pulse came down to normal; the blood culture became sterile, and by the 16th the perineum was healed, the uterus involuted, and the patient felt well. Administration of preparation X was discontinued and the patient was discharged on February 22nd. The total quantity of X, at the rate of 2 drachms given twice daily for twenty-seven days, was 13½ oz.

CASE II.

The patient, a primipara aged 24, had a normal labour at her own home on January 15th, 1929; there was a perineal tear. The next day her temperature was 100° F., and on the 17th the perineal sutures were removed owing to sepsis.

She was admitted to hospital on the 18th, her temperature then being 102.6° F., her pulse rate 124, respiration rate 26; she was very thin, with flushed cheeks, had diarrhoea, and complained of a dull ache in the lumbar region. A perineal swab showed the presence of *Staphylococcus albus* and *Streptococcus haemolyticus*; a swab from the cervix showed *Streptococcus haemolyticus*, and *Streptococcus haemolyticus* appeared in a blood culture in twenty-four hours. Quinine hydrochloride (5 grains in 10 c.c.m.) was administered intravenously every other day for three doses, and 5 grains in 1 c.c.m. intramuscularly on four alternate days.

Administration of preparation X by mouth in 2-drachm doses twice daily was started on the 21st; on the 22nd the patient had a rigor followed by drowsiness; she was tender in the right iliac fossa. On the 24th the temperature was 102° F.; the right wrist, the dorsum of the right hand, and the right elbow were swollen and tender. On the 29th an abscess over the right wrist was incised and thin yellow pus was evacuated. Shortly after, tenderness was noted over the right thigh, and though the wrist healed the pulse remained rapid and the temperature at about 102° F. On February 11th there was a swinging temperature from 99° F. to 103° F., the pulse rate being 120. Blood cultures were sterile on the 12th, but on the 18th an abscess over the right hip was aspirated and thin yellow pus was obtained. On the 20th the abscess was incised and a large quantity of pus was evacuated. The patient's temperature was still swinging, and on the 24th it rose to 104° F., the pulse rate being 140. She began to have pain in the left hip and swelling over the left buttock. On the 28th this swelling began to subside, but the temperature still swung from 98° F. to 102° F.

On March 2nd the temperature was normal for twenty-four hours. The wound over the right hip started to heal rapidly and was healed on the 15th, when the temperature had been normal since March 1st. On March 16th the patient was discharged, having taken in all 21½ oz. of preparation X.

CASE III.

The patient, a primipara aged 18, was delivered of an anencephalic monster at her own home on February 1st, 1929, and eight hours later admitted to hospital with a retained placenta. Immediately after the manual removal of the placenta her temperature rose to 101° F., and 30 c.cm. of anti-streptococcal serum were administered. On February 3rd her temperature had risen to 101.4° F., her pulse rate to 108, and the lochia were profuse and offensive. A perineal swab taken the following day showed on culture the presence of *Staphylococcus aureus*, *B. coli*, and *Streptococcus haemolyticus*, and *Streptococcus haemolyticus* was grown from a blood culture in twenty-four hours. Her temperature was now 103.6° F., pulse rate 126. On the 6th a course was started of intrauterine injections of glycerin and glauramine, but on the 10th the temperature and pulse rate were still rising, being 102.2° F. and 138 respectively.

Administration of preparation X in 2-drachm doses twice daily was begun on the 11th; on this day her temperature was 102° F., pulse rate 140, and respiration rate 30. The following day she had pain and tenderness on the left side of the abdomen, and on the 15th follicular tonsillitis, and complained of stiffness in the joints. The following and succeeding days the stiffness in the joints continued and she had a swinging temperature, rising as high as 103° F. On the 18th, however, the blood culture was sterile and she felt better. From now, moreover, the temperature came down, becoming normal on March 3rd. On March 6th the administration of X was discontinued, and on the 16th, the temperature and pulse having been normal for several days, the patient was discharged. The total quantity of X administered was 12 oz.

CASE IV.

The patient, a primipara aged 23, had normal labour at her own home on March 1st, 1929, there was a perineal tear which was sutured. The following day she complained of feeling cold and of abdominal pain, and these symptoms continued until the 4th, when she was sent to hospital. On admission she had a temperature of 104° F., pulse rate 120, respiration 22, flushed cheeks, shooting abdominal pains, abdominal tenderness, most marked in the iliac fossae, distension, and diarrhoea. The lochia were profuse and offensive. On March 6th the perineal swab culture showed the presence of *Streptococcus viridans*, *B. coli*, and diphtheroid organisms, and *Streptococcus haemolyticus* was grown in a blood culture after forty-eight hours. On the 8th she had diarrhoea, marked dyspnoea, a temperature swinging from 100° to 104° F., a pulse rate of 140, and respiration rate of 48. On the 10th, the oral administration of preparation X having failed through the patient vomiting, a drachm was injected subcutaneously into the buttock. The temperature now was 104° F., and the pulse rate 128: the following day the temperature was 101.4° F., the pulse rate had risen to 160, and the patient complained of pain in the right chest. On the 15th subcutaneous injection of 1 drachm X was repeated, on the following day the patient's pulse was very poor in volume; she had marked dyspnoea and her condition was critical. Preparation Y was given by mouth, 2 minims hourly for twelve hours. Examination of the sputum showed the presence of pus, pneumococci, and non-haemolytic streptococci. On the 15th the respiration rate was 62 and respirations were very shallow. She had a troublesome cough, and the temperature and pulse remained high. On the 20th there was still dyspnoea, the bases of both lungs were dull on percussion, there was bronchial breathing, and fine crepitations were heard at both bases. On the 22nd blood cultures were sterile, and the patient began to feel better, had no pain, and less dyspnoea. Signs of consolidation of both lungs persisted, and on the 23th there was absolute dullness at both bases, tubular breathing at the left base, and moist rales and faint breath sounds at the right base. On the 31st administration of preparation Y was discontinued and capsules each containing 2 minims of X were given once hourly for twelve hours over a period of eight days. On April 2nd there was absolute dullness over the

right base, and breath signs were very faint. The temperature ranged from 97° to 99°, the pulse rate was 90, and the respiration rate 20. On April 9th pus was aspirated from the right chest and a portion of rib was resected for an empyema. On the 12th and following days the empyema wound drained freely, and on the 15th the temperature was normal. On May 1st the temperature was still down, the wound was draining slightly, and the patient's general condition was good. Altogether she had 2 drachms of preparation X subcutaneously and 3½ by mouth. Of preparation Y she had approximately 24 minims daily for seventeen days.

CASE V.

The patient, a primipara aged 23, had a normal labour at her own home on March 4th, 1929. She was well until the third day, when her temperature rose to 104° F., after which it ranged from 99° to 103° F. until March 22nd, when she was admitted to hospital. On the 23rd her temperature was 103.6° F., and her pulse rate 128; preparation X, given by mouth, was vomited. On the 24th a swab from the cervix showed the presence of *Streptococcus haemolyticus* in pure culture, and *Streptococcus haemolyticus* was grown in a blood culture in twenty-four hours. Two minims of preparation Y were given hourly by mouth for twelve hours, and an arsenobillon course was started; she was very drowsy. On the 26th her condition was brighter; her temperature was 102°, and the pulse rate 100. On April 3rd a blood culture was sterile, but the temperature was still swinging from 98° to 103° F., and the pulse rate was 100; on the 11th the temperature ranged from 98° to 102° F., but on the 14th it came down to normal and administration of Y was discontinued. On the 24th the temperature and pulse were still normal, and the patient was discharged on the 27th. Preparation Y was given in 2-minim doses for twelve hours during twenty-nine days; the total amount being 1 oz. Arsenobillon was given intramuscularly in doses of 0.3 gram, three being given on the first day, two on the second, and one each on the third, fifth, and seventh days. The total quantity was 2.4 grams.

It is clear that, impressive as are the results described, they are too few in number to allow the deduction that this form of treatment is specific in its nature for septicaemia. They do, however, warrant the belief that the animal experiments pointed correctly to the hypothesis that vitamin A plays a part as an anti-infective agent to bacterial infection, and has the property of raising the resistance of the body to such infection. The fact, observed above, that the administration of these preparations does not produce an immediate beneficial effect, and that this only becomes obvious after a week to a fortnight, according to the severity of the case, from the beginning of treatment, suggests that the fulminating type of septicaemia, which proves fatal in a few days, may not benefit by this treatment in its present form. This view can only be tested, however, by further investigation. If vitamin A should ultimately prove, as the result of further tests, even to approach in efficacy the standard obtained in the present work, it is obviously of great value as a therapeutic agent. Nor is there reason to believe that this anti-infective action, if established clinically, would only be of importance in streptococcal infections, and it is most probable that the same increase in bodily resistance would be found in many other types of infection. We think it desirable that clinical trials should be made in other bacterial infections. It is probable that the dosage of vitamin A and the mode of administration we have used can be improved upon by further trial.

Finally, if vitamin A should prove to have anti-infective qualities of a curative nature, as this work suggests, it must also be of inestimable value in its prophylactic effect. Indeed, it is possibly essential for the natural defence of the body against infective agencies, and, if so, it is incumbent to see that the body under all conditions, but especially in times of special stress, as in pregnancy, should receive an adequate and large supply of this substance by the inclusion in the diet of natural foods which contain it. Such foods include egg-yolk, green vegetables, milk, butter, and cheese. Cod-liver oil also contains vitamin A in abundance.

Summary.

On the basis of animal experiments which indicated that vitamin A is an anti-infective agent, we have treated five cases of puerperal septicaemia from whose blood haemolytic streptococci were grown, with preparations rich in vitamin A. All made complete recoveries, thus indicating that vitamin A, when given therapeutically, can raise the resistance of the human body against septic and infective micro-organisms.

The cases described were under the care of Mr. Ki... Mr. Chisholm, and Mr. Stacey, members of the honora... staff of the Jessop Hospital, Sheffield, and to them we w... to express our indebtedness. We wish also to thank Professor Miles Phillips for his interest in the work, and Miss Moore, the resident house-surgeon.

The investigation was carried out with the assistance of the Medical Research Council.

APPARENT RECURRENCES OF SCARLET FEVER.

BY

W. H. KELLEHER, M.B., B.Ch., D.P.H.,

SOUTH-WESTERN HOSPITAL, STOCKWELL, S.W.

THE difficulties which attend the diagnosis of mild types of scarlet fever can best be appreciated by those whose experience in this disease is greatest and who have been impressed with the need of maintaining very careful observation before arriving at a decision. The Dick test and the Schultz-Charlton reaction, though valuable, have not removed all diagnostic difficulties. A negative Dick reaction does not always exclude scarlet fever, nor when during the course of a disease the patient develops no immunity, as evidenced by failure to react to the Dick toxin, may it necessarily be assumed that he is convalescing from scarlet fever.

It is a well-established fact that a susceptible individual placed in a community which contains carriers of the diphtheria bacillus, or in which fairly frequent outbreaks of diphtheria occur, will develop immunity in a comparatively short time. May not, then, a susceptible person in an environment of scarlet fever acquire, through subinfective doses, a similar immunity? It is incorrect to assume that a person with a scarlatiniform erythema and a Dick-positive reaction who, in the course of two or three weeks among scarlet fever patients, fail to react to the Dick toxin is necessarily suffering from erythema due to the toxin of the scarlet fever streptococcus. Furthermore, it is usually in those cases where its help is most needed—cases, for example, with transient rashes—that the Schultz-Charlton reaction fails, though other signs present at the time and later developments may serve to indicate that the case was actually one of scarlet fever.

There are bound, therefore, to be many erythemata the nature of which cannot be established by the Schultz-Charlton reaction or a Dick test, and whose diagnosis must depend on an observation of the course of the disease over a fairly lengthy period. Valuable diagnostic aids are the occurrence of complications, such as albuminuria, cervical adenitis, arthritis, or otitis media, and a study of the appearance, order, and nature of the desquamative process. Even here, however, there are pitfalls. Many mild but undoubted attacks of scarlet fever, generally recognized only by their occurrence during an epidemic, are followed by little or no desquamation. On the other hand, there are many scarlatiniform erythemata which produce skin changes practically indistinguishable from those of true scarlatinal peeling.

DIAGNOSIS OF SCARLATINIFORM ERYTHEMATA.

The diagnosis of scarlatiniform erythemata prodromal to certain of the exanthemata will generally not cause difficulty for more than a day or two. These erythemata are generally followed by some other sign or symptom which helps to establish their nature. Similarly in the case of drug rashes the history, the disproportionate constitutional

disturbance, and the absence of enlarged tongue papillae, help to establish the diagnosis; moreover, these rashes are generally followed only by slight desquamation. The same points are of value in the investigation of erythemata suspected to be due to the action of certain food substances, additional help being sometimes afforded by the appearance of urticarial patches. The majority of enema and serum rashes may be diagnosed without difficulty. Perplexity is sometimes caused by the scarlatiniform rash, which may be seen on the second day of the rubella eruption, though the rubella which is marked enough to be mistaken for scarlet fever can, in the absence of other signs, usually be distinguished from it by the mild or absent throat signs and the appearance of the tongue. Later on the appearance of desquamation, which in rubella is never present on the palms and soles, and on the trunk is almost invariably of a branny or powdery nature, would usually clear up any difficulty.

The cases whose diagnosis may cause the greatest difficulty are those of recurrent scarlatiniform erythema. Associated with the erythema there may be slight pyrexia and a reddened throat; desquamation is usual, but is frequently of a branny type, beginning earlier and not lasting so long as the desquamation of scarlet fever. There may be a history of several similar attacks, and it is possible, therefore, that some of the cases of alleged recurrent scarlet fever recorded in the literature may have been of this type. Acute exfoliative dermatitis is similar, but the rapidity with which desquamation appears, and its coarse nature, are usually sufficient to differentiate this affection.

RECURRENT SCARLET FEVER.

Clinicians differ very much in their views as to the possibility of recurrence in scarlet fever. Goodall,[1] who has never seen more than two attacks in one person, doubts whether three or four infections ever occur. Foord Caiger has personally observed three genuine attacks. Rolleston[2] believes that recurrences may occur, and gives instances where competent observers have recorded third and fourth attacks. Everard[3] cites the case of a woman in whom he observed what was supposed to have been her fifth attack of the disease; in this woman the first attack occurred when she was 3 years old, and Everard mentions that it was complicated by chicken-pox and measles, all three rashes being present at the same time. As, however, measles may be associated with a papillated tongue, and chicken-pox and measles with prodromal scarlatiniform rashes, it must, in the circumstances, have been difficult to establish the diagnosis of scarlet fever. In this patient the second infection occurred when she was 7 years old, and the third and fourth, which appeared after an interval of nine and ten years respectively, were complicated by rheumatism. The fifth attack was observed by Everard personally and appears to have been genuine scarlet fever, as the patient and her niece developed the disease on the same day, a week after they had been in contact with an established case. Fielding[4] records a case of a blacksmith said to have had five attacks in twelve years, the first occurring during an epidemic. On each occasion the syndrome comprised sore throat, strawberry tongue, intense rash, fever, and complete desquamation.

In view of the above observations it is interesting to record the case of a young woman who, in February of this year, was admitted to the South-Western Fever Hospital with what was alleged to be a fifth attack of scarlet fever.

This patient was first admitted in October, 1913, when she was 3 years old. She had a very bright rash, severe throat symptoms, and submaxillary adenitis. Desquamation, which was profuse, began at the tips of the fingers. Three weeks after admission she developed faucial diphtheria. She was in hospital for nine weeks, and I find from the case register that her case was diagnosed as one of scarlet fever.

In December, 1922, she was readmitted to a scarlet fever ward, and her case sheet records a general punctate erythema which appeared on the day of admission and was preceded by a sore throat, inflamed but clear fauces, and a furred tongue. The next day the rash was very intense, but confined principally to the trunk. The throat, though clear, was very congested, and the tongue was peeling at the tip and edge. There was no adenitis. Twenty-four hours later the erythema was unchanged, but the tongue had almost finished peeling. Ten days after admission there was peeling of the chest, and, at the beginning of the fourth week, of the legs and feet. Desquamation appears to have finished at the end of the fourth week, when the patient was transferred to the convalescent home from which she was discharged as recovered two weeks later. The diagnosis was scarlet fever.

In August, 1926, the patient was admitted to the Grove Fever Hospital with an erythema confined to the trunk and legs. The Schultz-Charlton reaction was negative. The temperature was 100° F.: she had a sore throat, slight faucial injection, a furred tongue, and circumoral pallor. The next day the temperature was 102 F., but two days later the rash had faded, the tongue was clean, and the papillae were enlarged. Desquamation began at the end of a fortnight, and was general by the middle of the fourth week. There were no complications, and the patient was discharged at the end of seven weeks. The diagnosis was again scarlet fever.

The next attack, which appears to have been a mild one, occurred in December, 1927, and the patient was admitted to the Joyce Green Hospital. On the previous day she had suffered from headache and general pains, but made no complaint of sore throat. The rash appeared first on the neck, and when the patient was seen on admission she had a general punctate erythema, a coated tongue, a clean but injected throat, and a temperature of 99° F.; there was no adenitis. By the next day the rash had faded, and nothing else occurred worthy of note until about three weeks after admission, when desquamation appeared on the hands and feet. The patient was then transferred to the Southern Hospital. There were no complications, and she was discharged at the end of the fifth week—her case diagnosed as one of scarlet fever.

On February 23rd of this year she was again admitted to the South-Western Hospital. Two days previously she had had a slight rigor, followed on February 22nd by backache. On the morning of the 23rd she complained of headache and nausea, and a rash appeared on the neck which, on admission that evening, had developed into a general punctation, with a more discrete appearance on the face. The limbs were unaffected; glands in the posterior cervical fossa were palpable, but nits were present on the scalp. There was no sore throat, but the fauces were slightly injected; the temperature was only 99° F. On the following day the circumoral region was invaded; also the limbs. Here the rash appears to have been paler, though still of a punctate character. The tongue was coated, and the papillae at the tip were enlarged The Schultz-Charlton reaction was negative. Five days later desquamation was noted on the neck, and twelve days after the patient's admission desquamation of the pinhole type was seen on the legs, with a coalescence into larger patches, and was followed the next day by peeling of the fingers. Desquamation rapidly assumed the character typical of scarlet fever, involving every part, with the exception of the terminal phalanges and the backs of the hands. The peeling on the hands was profuse and lasted for about three weeks; the toes and soles of the feet were not involved. There were no complications, and the patient was discharged after five weeks in hospital.

CONCLUSIONS.

There would appear to be no doubt as to the genuineness of the first attack, and in the second also the signs and symptoms present warranted the diagnosis of scarlet fever. There seems to be some slight doubt about the nature of the rash in the third attack, but the subsequent peeling conformed more to the scarlet fever type than to that of recurrent scarlatiniform erythema. The fourth attack was very mild, but though the rash was fleeting there was no doubt about its character. Most practitioners have seen cases of undoubted scarlet fever in which the rash, accompanied by a few symptoms and signs, has shown itself for just as brief a period. As for the final attack, few observers, seeing it for the first time after desquamation had started and watching its progress, would have failed to arrive at a diagnosis of scarlet fever.

The patient's history gives no reason to implicate drugs or enemata in the causation of her attacks. In the intervals she never suffers from rashes of any description, nor does her skin ever show signs of dryness or of definite peeling. Her work is very light and insufficient to give rise to desquamation from the hands during prolonged periods of rest. Her previous illnesses include measles, chicken-pox, and whooping-cough. There are several young persons in the family who, it appears, have not suffered from scarlet fever.

BLOODLESS TONSIL ENUCLEATION.

A MODIFIED TECHNIQUE AND A NEW GUILLOTINE.

BY

O. POPPER, F.R.C.S., M.B., CH.B.EDIN.,

FIRST ASSISTANT, ROYAL EAR HOSPITAL, UNIVERSITY COLLEGE HOSPITAL.

TWENTY years ago Whillis and Pybus published their now classical technique of guillotine enucleation by the reversed method. It has been universally adopted, though often incorrectly ascribed to Sluder, and its position remains unchallenged and is likely so to continue.

Some three years ago it occurred to me that if "traction" could be applied to the posterior aspect of the tonsil during the dislocation manœuvre of the Whillis and Pybus technique, the deep fibrosed or so-called "difficult" cases could be more easily dealt with. To this end I had the distal rim of the fenestra of my guillotine made in the form of a series of miniature sharp chisels. The guillotine head is inserted from below upwards, behind the tonsil and in front of the posterior pillar. The lower pole of the tonsil is threaded through the fenestra, and the tonsil is elevated to bulge the anterior pillar in the usual way (Fig. 1). The little chisels have now dug themselves into the postero-lateral aspect of the tonsillar capsule, and fix it in a harpoon-like manner. The next step is designed to pull the tonsil out of its bed, thereby stretching the peritonsillar tissue; the tonsil, being fixed, will not slip off the guillotine, and traction is applied to it by retracting the guillotine towards the mid-line and slightly forwards—that is, away from the posterior pharyngeal wall (Fig. 2). Slight counter-pressure is exerted with the thumb over the tonsil. With the guillotine maintained rigidly in this position the whole tonsil is inverted through the fenestra and the blade driven home behind the anterior pillar (Fig. 3). It will be seen that apart from the "traction" the whole manœuvre, which takes but a few seconds, is the ordinary Whillis and Pybus technique.

FIG. 1.

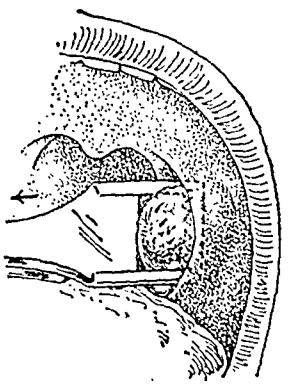

FIG. 2.

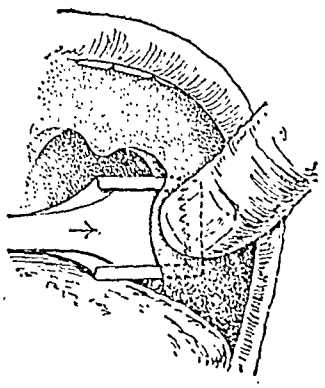

FIG. 3.

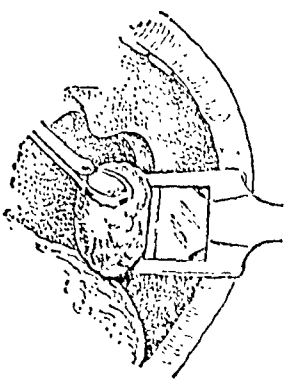

FIG. 4.

Up to this point the operation is bloodless if a blunt guillotine is used. By the ordinary method the tonsil is now severed from its bed—and, according to the nature of the case, the bleeding may be more or less severe. Whether the mode of severance be in the nature of torsion or avulsion, the stump is invariably torn away deep to its crushed portion, hence the inadequate haemostasis.

A single blade cannot be expected to perform both the functions of crushing and of cutting. For this purpose a well-designed two-bladed guillotine is essential. I have made use of such an instrument, and, as is indicated by the main title of this communication, the whole operation can be rendered bloodless.

Where the ordinary guillotine technique *plus* "traction" is employed many tonsils, which in the ordinary way would call for dissection, can be dealt with by the guillotine. The surgeon, however, will prefer to dissect—especially adult cases—unless he can be sure that the immediate haemorrhage incidental to ordinary guillotine procedure can be controlled.

The question which must be decided is not "Can one guillotine?" but "Should one guillotine?" I think it can be fairly stated that guillotining is the cleanest method, and, if haemorrhage is slight, recovery is rapid and healing perfect. The latter is only natural when one reflects that with the guillotine there is the minimum handling and trauma of tissues as compared with even the most immaculate dissection.

When we examine the peritonsillar tissue in a case of chronic tonsillitis we find masses of fibrous tissue with vessels running through it. Obviously, when cut through, these would gape. In the child the peritonsillar tissue is loose and elastic; the vessels here involute naturally, and bleeding is minimal.* The decision as to whether to guillotine or dissect tonsils therefore rests very largely on the question of the amount of bleeding anticipated.

It is obvious that where there has been peritonsillar fibrosis considerable force is required to crush the vessels adequately. In the instrument presently to be described such crushing force can be exerted. There are a certain number of cases where the tonsil is so firmly bound down that it is impossible to invert it completely through the fenestra of the guillotine. Here, of course, dissection is the only method.

When the blade of the guillotine is driven home the tonsil lies isolated, separated from its bed by the blade, the crushed stump intervening (Fig. 4). This stump, in the properly performed operation, consists of the circumferential reflection of mucous membrane surrounding the *equatorial area of the tonsil* at the junction of its embedded and non-embedded portions, together with some areolar and fibrous tissue, and vessels of the tonsillar bed.

There are several types of two-bladed guillotines incorporating crushing and cutting blades. I have found them most satisfactory, particularly that of La Force. In this guillotine a very powerful crushing force can be applied, to which I ascribe the perfect haemostasis that is obtained. The mode of bringing its crushing and locking action into play is clumsy; furthermore, the fact that the cutting blade requires to be carefully reset after each tonsil has been removed is a grave fault, and no doubt these two disadvantages account in a large measure for its lack of popularity in this country.

I have developed the two-bladed guillotine illustrated, the crushing power of which is very great and instantaneous. It locks automatically; moreover, no strain is put on the surgeon's memory. The cutting blade sets itself back automatically when the crushing blade is released, the recoil being utilized as in the Maxim gun. This is an extremely important feature—as the cutting blade is merely a convenience and must at no stage of the operation obtrude itself or add to the complexity of handling the instrument—if one is to claim that this two-bladed guillotine is almost as simple to use as the ordinary single-bladed type. The cutting blade in the instrument cannot be sent home first—a procedure that would negative the bloodless object of the operation.

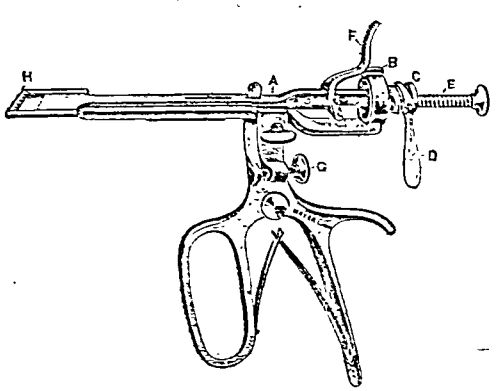
The principle of the guillotine is similar to that of the guillotine devised by Ballenger, Elphick, Howarth,

* See author's article in the *Journal of Laryngology and O*. September, 1926.

La Force. There are two blades, one the crushing blade (A), and the other the cutting blade, which lies between the bed plate and the crusher and works close up to it. The crusher, which grasps the stump of the tonsil, is primarily actuated by the handles with such pressure as may be brought to bear by the strength of the grip of the hand. This action automatically engages the mechanism (BCD) for the final crush—a useful time-saving feature.

This mechanism is in the form of a pair of double cylindrical circumvolutes, the internal or female (B) being attached to the bed of the guillotine, and the external or male (C), which has a lever (D) attached, is fitted and rotates freely on the crushing blade and is kept in position by means of a spring (E).—A quarter turn of the lever (D) tends to drive the crusher further forward and exerts extra pressure and automatically locks it and completes the crushing operation. The mechanical advantage being about 1 to 14, the crushing effort is very great. The cutting blade is attached to the crusher, and the final cutting is performed by the depression of a lever (F) which drives the cutting blade forward. The releasing of the guillotine brings the lever (F) of cutting blade in contact with the stop on (B) and automatically throws it out of action and sets the cutting blade ready for the next operation.

It will readily be seen that it is not possible for the cutting blade to be brought to action until the crushing



blade has done its work. Miniature sharp chisels are on the distal rim of the fenestra (H). The purpose of screw (G) is to set the blades at any desired position in order to vary the size of the fenestra. Thus one guillotine will do for all cases except for children under 2 years. The guillotine is shown set for a small tonsil.

The actual handling of the guillotine is simplicity itself. When the tonsil has been completely inverted (Fig. 3) the crushing blade is sent home by compressing the handle, and lever (D)—already partly engaged—is pushed over to its limit with the free hand in a clockwise direction. After a suitable period the tonsil is secured with a vulsellum and is cut off the guillotine by depressing lever (F) (Fig. 4). Lever (D) is then returned to its original position and the guillotine will spring open and be already set for the other tonsil.

It is obvious that if the crushing pressure is maintained until coagulation has taken place an added safeguard is incorporated. Accordingly I crush the stump for three to five minutes before removing the tonsil. If the mouth is large enough and a second guillotine available the other tonsil can be dealt with while the first still crushes its stump. There will be no bleeding—merely a moistness of the tonsillar bed.

If desired, the stump can be ligatured in a dry field—an easy matter. The whole operation in adults takes ten minutes at the outside. In children, where the peritonsillar tissue is soft and elastic, momentary crushing suffices to secure complete haemostasis. I have used the instrument illustrated for almost a year at the Royal Ear Hospital, University College Hospital. In not a single case has there been any primary reactionary or secondary haemorrhage.

Irwin Moore, quoting McNab, and referring to two-bladed guillotines, complains that the anterior pillar is frequently removed. The type of guillotine used is not stated. I can only say that with the technique indicated I have not been able to emulate this. The anterior pillar comes through the ordeal uninjured—provided the fenestra of the guillotine is not too large for the tonsil. Even in that case the expert will manage not to invert it completely through the fenestra. It is, however, definitely an advantage to adjust the fenestra slightly on the small side, which can be done instantly in the instrument illustrated.

The criticism has been made that reactionary haemorrhage occurs a few hours after the operation with two-bladed guillotines. I have not encountered this, and can only assume that the instrument used did not allow sufficient crushing force to be applied to the stump.

Children whose tonsils have been removed by this method show no, or only very slight, rise of temperature. This I attribute to the obliteration (by crushing) of the lymphatics and subsequent minimal toxic absorption from the open tonsillar wound.

I wish particularly to acknowledge my indebtedness to my friend Mr. Phelps, of Messrs. Mayer and Phelps, and to their technical staff, for the great assistance and the facilities extended to me.

TONSILLECTOMY.

BY

H. NORMAN BARNETT, F.R.C.S.,

SURGEON TO THE BATH, EAR, NOSE, AND THROAT HOSPITAL.

IT is not desirable that one method, and one method only, of performing the operation of tonsillectomy should be adopted for patients, whether adults or children. Each case is a law to itself, and should be judged on its merits. If this mental attitude is adopted it will save the unwary and the comparatively inexperienced operator from many pitfalls.

To attempt to remove the deeply embedded adherent tonsil which has been the site of many attacks of tonsillitis, and perhaps the subject of abortive attempts at removal, by the guillotine only, or even with a finger on the pillar, or traction by tonsil forceps, will only lead to disappointment for the patient and the operator. For the tonsil will not move by finger pressure, and the forceps will take away a superficial piece of tissue, but will not remove the main mass of the gland from its strong anchorage.

Another subdivision of this sort of tonsil, met with in even young children, is that in which the pillars have met in the median line in front, and are indistinguishable from the underlying tonsil. This type is also the product of long-continued chronic inflammation with interludes of acute tonsillitis. The tissues are usually very septic, and the tonsil when reached is generally found to be lying in a pool of pus. For such tonsils dissection or partial dissection should be employed.

It is of advantage to employ a tonsil forceps, such as that made for me by Messrs. Mayer and Phelps. The

FIG. 1.—The Author's tonsil forceps.

advantage of this instrument is that it need not be removed during the operation, since, by means of the ratchet, it retains its hold, thus freeing a hand. Moreover, the handles will pass through the ring of the guillotine, if it is desired to use this instrument. (Fig. 1.)

The dissector best suited for this type of tonsil is one with a short curve and a cutting edge, the other end being

blunt and having a large curve. The pattern illustrated is also made for me by Messrs. Mayer and Phelps. (Fig. 2.)

If the pillars meet in a continuous fold in the median line an incision should be made at about the mid-point, each pillar in turn being held by special forceps and gently dissected off the tonsil for a short distance; the forceps then grasp the tonsil and traction is made upon it. If the pillars do not join in the median line, the tonsil forceps may be applied at once, and traction exerted till the line between the capsule and the posterior tissues is seen, when the curved cutting edge is inserted firmly, but with care, and the capsule separated from the surrounding tissue with short sweeps. When this has been accomplished the instrument is reversed, and the blunt large

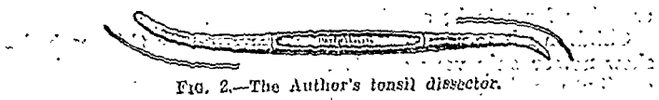


FIG. 2.—The Author's tonsil dissector.

curved end is used in the same manner to separate the posterior part of the tonsil; the guillotine is threaded on to the tonsil over the handles of the forceps, and the final enucleation is effected by that instrument. This combination of the dissector and guillotine I find to be more satisfactory than complete removal by dissection. It is more rapid, and leaves a smoother surface to heal; the parts are more comfortable after operation, while there is less likelihood of haemorrhage. If, for any reason, however, the guillotine is not desired, the dissection may be completed in the ordinary way, bleeding being controlled by pressure forceps.

For the type of tonsil which is prominent and not adherent, and in which the pillars of the fauces are easily separated, the guillotine is the instrument of election. Dissection is unnecessary, and even mischievous, for it requires deeper and more prolonged anaesthesia, with more dragging on and handling of the pillars; the parts are more uncomfortable after the operation, and heal more slowly. In this type of tonsil the guillotine alone may be used for enucleation, or, again, its action may be aided by the tonsil forceps. The guillotine should be very blunt, and if it be sufficiently so the need for the expensive complicated crushing guillotines does not seem to exist. The most useful form probably is Heath's modification of Mackenzie's pattern.

A good deal depends on the illumination and view of the parts for successful operation, and these will be best secured by wearing an efficient headlight and using Spencer's gag, a tongue clip, and a strong tongue depressor with a long handle, such as Seymour Jones's.

Haemorrhage is a constant source of discussion in tonsil operations. If it is confined to slight capillary bleeding it may be disregarded during the operation, and in very septic conditions is beneficial. If it impedes operation it may be mopped or removed by suction with a suction-anaesthetic apparatus. After the tonsil has been removed the bed should be immediately filled with a firm sponge or mop, and pressure kept on for a short time. On removal of the pressure there will, as a rule, be no haemorrhage; if, however, a main artery is bleeding, a ligature should be applied, while if multiple capillaries are still bleeding the pillars should be stitched. If bleeding is profuse from a large number of vessels owing to low coagulation power of the blood, pressure should be continued while 10 c.cm. of horse serum and 1/12 to 1/4 grain of morphine, according to age, is injected. When such haemorrhage is controlled the pillars may be stitched, though this, as a rule, is not necessary. In bleeding of this type recurrence in a modified degree may take place, when a second or even a third dose of horse serum may be injected.

If the anaesthesia is to be short the second tonsil may be proceeded with while pressure is kept up in the bed of the first; but with long anaesthesia the first tonsil bed should be dealt with where necessary before enucleation of the second tonsil is begun. The best anaesthetic for removal of adherent buried tonsils in adults and children is ether, or ether three parts to chloroform one part, by the open method. In children ethyl chloride is an admirable anaesthetic when the tonsils are prominent and not adherent, or adherent only to a moderate extent; in certain adult tonsillectomies also, when the tonsils are very free or rapid short anaesthesia is required for any reason, ethyl chloride may be recommended.

It is frequently found that the turbinate bodies obstruct the airway in those with enlarged septic tonsils, and a routine examination for this should be carried out. When found, submucous fracture should be done. A convenient

FIG. 3.—The Author's instrument for submucous fracture of the turbinate bones.

form of instrument for this purpose is that made for me by Messrs. Mayer and Phelps. If this is done it is not, as a rule, necessary to remove the posterior ends of the turbinate bodies.

The operation of tonsillectomy, by whatever method, should be considered as a major procedure and left in the hands of the specialist. It is, however, recognized that circumstances often lead to its being performed by others, and to them the following suggestions are made.

Never approach the operation as a small easy procedure devoid of danger. Use ether, or one part chloroform to three parts of ether, as the anaesthetic, rather than ethyl chloride, as the latter requires an expert anaesthetist, trained assistance, and a special inhaler. Lower the head on an inclined plane. Don't hurry, but calmly examine the extent of the tonsil to be removed by strongly depressing the tongue. Grasp the tonsil with a strong pair of tonsil forceps passed through the ring of the guillotine, draw it from its bed, and thread the guillotine on to the tonsil from below, upwards and outwards. Press the distal end of the instrument firmly into the tonsil bed. Push down the blade of the very blunt guillotine to compress strongly the neck of the tonsil. Remove the forceps; carry the handle of the guillotine across the mid-line of the body and then twist the instrument half round. These movements get the tonsil from its bed and compress and twist the vessels that supply it. Drive the blade home and remove the tonsil. Insert at once a mop on a long holder in the tonsil socket, and keep up pressure for a couple of minutes; then gradually remove the mop. If, as is usually the case, there is no haemorrhage, proceed to remove the second tonsil, giving a little more anaesthetic first if required. If there be haemorrhage, deal with it by ligature, stitching the faucial pillars, or by injections of horse serum and morphine as circumstances demand.

A NOTE ON THE TREATMENT OF ASTHMA.

BY

A. GUNN AULD, M.D., M.R.C.P., D.P.H.,

FORMERLY LECTURER ON CLINICAL MEDICINE AND PATHOLOGY, NORTH-EAST LONDON POST-GRADUATE COLLEGE.

CASES of hypersensitiveness, of whatever kind, have of late been brought more closely into union. Some pathologists considered that anaphylaxis and anaphylactoid shock were entirely different phenomena. But physicians are bringing them into near relationship. Kolmer suggests that "enough acceptable data have now been accumulated to permit of at least a partial classification and house-cleaning of terms and ideas." He thinks that for all cases of hypersensitiveness the best term is "allergy," and objects to any classification based on our ability or inability to transfer passively the antibody, as it may be present only in the cells. He adds that "we may safely assume that precipitin and allergic antibody are not identical." I came to the same conclusion long ago.[1]

Barber and Oriel[2] remark that

"the important fact is that many of the symptoms to which sensitized persons are liable are identical with those to

animals suffering anaphylactic shock, for example, contraction of the pilomotor muscles with erection of hair follicles, sneezing and coughing, pruritus, urticaria, respiratory distress," etc.

Again, Dale and Kellaway[4] found that the injection of an anaphylactic guinea-pig (to egg albumen) with agar sol in a small dose resulted, within a minute following the injection, in symptoms "presenting in their type and rapidity of their fatal issue a close resemblance to true anaphylactic shock." Then the work of Lewis[5] shows that in all anaphylactic and anaphylactoid reactions a fundamental factor is the liberation of an H-substance, which is probably histamine. Pickering,[6] in his recent work on blood plasma, says:

"In many respects the condition of the blood in anaphylactic shock resembles that produced by the intravascular injection of peptone. The shed blood is clotted by the passage of CO_2, by dilution with water, by acidification, and by the addition of tissue extracts. . . . The capacity of the plasma to aggregate platelets is increased and may be evident *in vivo*. Parallelism of behaviour is also apparent in the suppression of anaphylactic and peptone shock. The previous intravascular injection of hirudin, of sulphate of atropine, or of chlorhydrate of choline, prevents or mitigates both these reactions."

Zinsser[7] says:

"It would be a pity if the erection of a fence of division at the present time should influence investigators to overlook fundamental similarities, although we are faced with a large variety of supersensitive states."

Sometimes the animals inoculated are more sensitive to the poison than are the controls; they have become allergic. He considers this allergy a "paradox phenomenon," and a most ingenious adaptation of the side chain theory was applied to it by Krietz in 1902 and by Wassermann in 1904—namely, that in the state of allergy the receptors had not been cast off from the cells, these sessile receptors rendering the cell more exposed to toxic action than it was normally, and more susceptible to injury.

Perhaps I may be allowed to state that I published the same view in 1901.[8] In my investigation of the pneumococcus at the old Embankment Laboratories, I found that no antitoxin was produced by injection of the toxin, in whatever quantity, but that, on the other hand, the animals were allergic. I remark:

"Why is no antitoxin produced, and what is the immediate cause of the sensitiveness? So far as our knowledge goes, these phenomena must be regarded as mutually dependent. On Ehrlich's theory we must have an excessive accumulation of side chains in the susceptible cells, and likewise *the failure to cast them off into the blood as antitoxins*. Such overloading of the cells would, of course, cause their injury and so render them more susceptible to fresh doses of the toxine. . . . It may be legitimate to consider that the short time which elapses between the anchorage of the haptophore group, and the coming into play of the toxophore group, in the case of the toxine of pneumonia, may prevent the cell from acquiring the power of throwing off its side chains in a sufficiently free manner."

Diet and Protein Testing.

It must be remembered that in cases of allergy, although one particular part seems to be affected, the whole body participates. Hence local measures are not usually of much use. I am entirely opposed to the idea that asthma is a neurosis. My asthmatical patients are much less neurotic than normal individuals. As Freeman[9] remarks, we have the Kustner-Praussnitz reaction; how do the psychopathists explain this? M. Walzer[10] states that a detectable amount of certain types of protein enters the blood from the digestive tract regularly in the average normal individual. The same thing was noted by Freeman[11] on himself. He punctured his middle turbinal with the serum of a person sensitive to eggs, and some time after ate an egg. Shortly the punctured nostril showed great irritation, indicating that the albumen had passed through his blood. When the protein is entirely digested the sensitized site remains unaltered. From this it will be seen how important is the diet of the asthmatic. He should be limited in his proteins, and whatever he eats should be tested on his skin, although this test is not by any means sure. He should take light meals and nothing after 7 or 7.30 p.m., if possible. Also, the bowels should be kept open. I usually test the skin with sixty to seventy different proteins in groups of five (Warren Vaughan says the scratch should be three-eighths of an inch), but it is remarkable how many adults give no reaction, although, of course, they may be sensitive to some substance which may be revealed on making careful inquiry into their lives.

Peptone and Serum Peptone.

Last summer I made some very careful experiments with serum peptone. I added the peptone to the drawn blood, mixed it slowly, and incubated at exactly 37° C. for two hours. I let it stand until the next day, when a beautifully clear serum peptone had come out. The next time I tried it the serum peptone made under exactly the same conditions had coagulated. This was disappointing, as I had a high opinion of the serum peptone. Several different bloods were tried, and some came out well, others did not, so I usually made agar serum peptone, but with this difference, that instead of adding phenol as a preservative I now always employ chloroform, as it gives a clear mixture for a considerable time. I may add that the patient should be without food for five hours previously. The drawn blood is kept at room temperature until the next day, when the serum is pipetted off and mixed with solution of agar in very minute quantity (one-fifth of a 1 in 1,000 solution to four-fifths of serum). The agar serum solution is put in the incubator for two hours at 37° C. Then peptone (4 c.cm. of a 30 per cent. solution or 6 c.cm. of a 20 per cent. solution) is mixed with each ounce, and three or four drops of chloroform are added; mix with half its volume of water before injecting. It is not so much the serum as the anaphylatoxin produced which influences the patient. It was shown by Dr. Anrep at University College that the agar serum so prepared was poisonous to guinea-pigs, while ordinary serum was not. Full details will be found in former papers of mine.[12]

It may be hardly necessary to add that while some patients respond well to peptone others do not. This may be owing to the state of disintegration of the colloidal particles of the blood and tissues in allergy. Pickering[13] states that "peptone unites with plasma and forms a relatively stable compound which resists disintegration." This colloidal stability may be overcome in some cases, but not in others. I have clearly stated the sort of asthma cases which resist peptone, and I need not repeat them here. An American physician[14] lately published a paper in which he condemned my peptone treatment and also that of all other observers. He took five patients with asthma and gave 0.5 c.cm. of peptone 5 per cent. to them intravenously once a week for four weeks; to another five he gave 1 c.cm. intravenously once a week for eight weeks. He says there was some improvement in those treated in this way, but not in those treated by other methods. Now how can anyone expect to reduce asthma in this mechanical manner, with only four and eight doses, and such small ones? One must begin with a small dose (0.3 c.cm.) and work up to 3 or 3½ c.cm., and only in cases suitable for the treatment.

If intravenous treatment by peptone is not very successful, agar serum peptone should be tried (1 c.cm. up to 4 c.cm.). In a good many cases a cure has been effected by the latter substance after peptone had failed. If a patient is nervous about having his blood drawn the serum of another healthy person about the same age will suffice, though it may be as well not to inform the patient of this.

Ultra-violet Rays and Radiostol.

Last summer I began to use the ultra-violet rays in several ways. I irradiated the agar serum peptone for a quarter of an hour at a distance of eighteen inches from the mercury vapour light. If there is any blood in the serum it may coagulate. The results of this I believe were good. I also irradiated the chests and backs of the patients in a number of cases, and my opinion of this treatment was very favourable. I give it in all cases now when possible. The mercury vapour lamp I use is a Cemach stand model, which gives a powerful general light; and for an applicator there is the special mounting devised by Dr. Cemach of Vienna for the Kromayer lamp, providing both vertical and horizontal travel of the hood and burner by an independent rack and pinion movement in both directions, facilitating the delicate technique necessary for orificial application. For intranasal treatment, which

is all I use it for, this is quite satisfactory, and it is unnecessary to use a Kromayer lamp.

For general treatment I begin by exposing the chest and back twice a week to the light at three feet distance. The first time 1 minute, the same for the back; the next time 1½ minutes, then 2 minutes, then 2½ minutes, then 3 minutes, then 3½, then 4, then 4½, then 5, then 5½, then 6, then 6 minutes. Some patients easily take somewhat longer periods, but I doubt if it is any use. This is the first course. Then the patient waits for a month, when the second course of twelve treatments is given. One of the most successful cases I had was that of an elderly lady who had been treated by me and others for many years with all sorts of things, and she would only respond for a short time. Since her second course she has had no asthma. This is now nearly four months ago. She had no other treatment. In another case a lady who had spasms practically every night was relieved for two months, when the spasms returned. She also took 50 tablets of radiostol, nothing else. In many other cases I have given agar serum peptone and radiostol. The radiostol I first used was a glycerin solution in 1 c.cm. ampoules. A few drops of water were mixed at the time of using, and it was then sucked into the syringe. To this the agar serum peptone was added, and it gave very good results. I shortly afterwards gave one tablet of radiostol daily. The radiostol is not equal to the ultra-violet rays, although both (and especially radiostol) much increase, amongst other things, the phosphorus in the blood, which is favourable for asthma.

Glucose and Insulin.

It is well known that the liver plays a part in asthma, as by it the toxic products of bacteria with undigested protein are rendered non-toxic, and it transforms albuminous products into urea, etc. It was suggested by Barber and Oriel[13] that the giving of glucose would in many cases strengthen the general function of the liver, enabling it to assimilate glycogen, etc. Some time previous to their paper, the giving of glucose was suggested to me by Dr. Parkes Weber. I have given it in a good many cases, and I believe with advantage. It may be given alone or with a little insulin. Several have noted the benefit derived from insulin; there is an increase of appetite and a sense of well-being in non-diabetic cases. MacLean finds it excellent in cases of malnutrition. He gives five units twice daily—before breakfast and before dinner. Along with this he gives one ounce of glucose, mixed with an equal part of orange juice at intervals of an hour after each dose of insulin. A good deal of starch is given with meals. The insulin is gradually increased to ten or twelve units, and the treatment kept up for three or four weeks. I have often given the glucose and insulin in this manner, along with ultra-violet rays and agar serum peptone, and in some cases the mixed coliform vaccine, in small doses twice a week, as recommended by Coke. I usually found this very good. The vaccine seems to act prophylactically. In one case, in the St. Marylebone Hospital[*] I treated a very thin woman, aged 37 (who for many years has had violent attacks of asthma near her menses), with glucose and insulin, ultra-violet rays, ovarian extract 5 grains daily, thyroid 1 grain daily, and her own blood (autohaemotherapy), 5 c.cm. of which mixed with 1½ c.cm. of peptone was injected immediately into the upper arm. She also had weekly doses of the vaccine. She practically recovered and was sent to a convalescent home.

A CASE OF CUTANEOUS DIPHTHERIA AS THE CAUSE OF AN OUTBREAK.

BY

ARTHUR MASSEY, M.D., D.P.H.,

AND

GLADYS J. C. RUSSELL, M.B., D.P.H.,

LEEDS.

To Chomel is credited the first reference (in 1759) to *dermatitis diphtheritica*. Some seventy years later Trousseau made fuller investigation of the disorder, Neisser first explored the condition bacteriologically, Jenner[1] mentions a case of diphtheritic infection supervening upon a chronic pemphigus, also two cases of ulcer of the leg with superimposed diphtheria. Slater[2] recorded a case of chronic cutaneous diphtheria. Knowles and Frescoln[3] collected reports of cutaneous diphtheria cases, which incidentally illustrate the diversity of clinical appearances capable of being presented by the condition. Barber and Knott[4] and, later, Perry[5] described cases of chronic diphtherial ulceration of the skin. Greenbaum[6] contributed a case of primary cutaneous diphtheria of the face. Goodall and Washbourn[7] mention cases of primary dermatitis diphtheritica affecting the fingers. The invasion of wounds by Klebs-Loeffler bacilli is a rare occurrence to-day, though at one time not so uncommon.

Dermatitis diphtheritica may be primary or secondary A breach in continuity of the skin is a necessary antecedent. The case now recorded was secondary to a faucial diphtheria, and infection was by auto-inoculation affecting a small area of intertrigo situated behind the right ear The case was responsible for the outbreak of faucial diphtheria outlined below. The outbreak comprised seven patients, all of whom were nurses employed at the Wythe Infants Hospital, Leeds. The bacteriological findings, in respect of the patients and domestic staff of the institution, were negative throughout. The sequence of case was as follows:

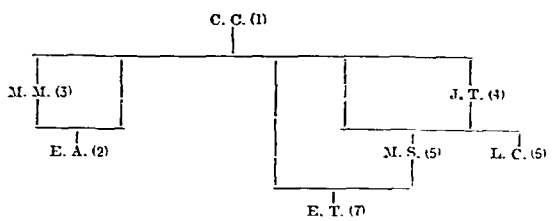
Case.	Patient.	Date Admitted to Isolation Hospital.	Bedroom Previously Occupied at Wyther.	Ward in which engaged at Wyther.	Remarks.
1	C. C.	23.12.28	No. 1	A.	Clinical diphtheria Resumed duty a Wyther on Jan. 23, 19
2	E. A.	15.2.29	No. 1	A.	Clinical diphtheria.
3	M. M.	17.2.29	No. 7	A.	Non-clinical diphtheria
4	J. T.	2.3.29	Sister's separate room.	A.	Clinical diphtheria.
5	M. S.	4.3.29	No. 7	A.	Non-clinical diphtheria
1	C. C.	Readmitted 6.3.29	No. 1	A.	Cutaneous diphtheria (see below).
6	L. C.	7.3.29	Lodgings; separate block.	B.	Clinical diphtheria Nursed Case 4.
7	E. T.	8.3.29	No. 7	A.	Non-clinical diphtheria

C. C. (Case 1) appears as the central figure in the outbreak. She was admitted to isolation hospital on December 23rd, 1928, suffering from faucial diphtheria. On discharge she resumed nursing duties at Wyther on January 20th, 1929. The outbreak proper began with E. A. (Case 2) on February 15th, 1929—that is to say, twenty-six days subsequent to the return to duty of C. C. Other cases followed, and, on March 5th, during the course of investigation, C. C. was found to have an area of intertrigo behind the right ear; it now transpired that this condition had been present, but had escaped notice, at the time of her discharge from isolation hospital on January 20th. The affected area of skin showed no outward manifestation of diphtherial infection, but nevertheless a swab was taken therefrom and was reported upon the next day as follows: "Bacilli present morphologically resembling K.L.B." A subsequent virulence test gave the following result: "On the third day there was a slight erythema around the site of inoculation; the sugar reactions were positive for Klebs-Loeffler bacillus; the result suggests an

organism of low virulence." Throat and nose swabs proved negative. Here, then, was a case of cutaneous diphtheria which the available evidence indicated as the source of infection. The patient was readmitted to isolation hospital on March 6th.

The lapse of twenty-six days between the return of C. C. from isolation hospital and the subsequent occurrence of the next clinical case (2) has to be explained. In this connexion M. M. (Case 3) might well have been infected first by C. C., for, being a non-clinical case, she was only discovered in the course of a general swabbing following the removal of E. A. on February 15th. Moreover, there might conceivably have been delay in the assumption of activity by the organisms of the original case. M. M. was removed on February 17th. At this juncture the swabs of all others were negative. On March 2nd—thirteen days after removal of M. M., J. T. (Case 4) was removed with clinical diphtheria, and a further general swabbing revealed M. S. (Case 5) as a case of non-clinical diphtheria, and the patient was removed on March 4th. As related above, C. C. was exposed on March 6th as a case of cutaneous diphtheria and was readmitted to hospital. L. C. and E. T. (Cases 6 and 7) followed on March 7th and 8th respectively, and there the outbreak ended. L. C. probably contracted infection from J. T., whom she had nursed prior to removal.

There appears to be no doubt that C. C. gave origin to the outbreak. Owing to the occurrence of certain non-clinical cases in which the date of initial infectivity was not determinable, it is difficult to outline the passage of infection from case to case, although it is essayed to do so in the tree below.



Our thanks are due to Professor J. Johnstone Jervis, medical officer of health, ...eds, for permission to publish the above particulars relating to an interesting case and its sequel.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

STRANGULATION OF OVARY IN AN INGUINAL HERNIA ASSOCIATED WITH CONGENITAL ABNORMALITY OF THE KIDNEY.

THE interest of the case here recorded lies in the close developmental relationship between the kidney and the ovary, in that they both arise from the Wolffian body. As it seems highly probable that a congenital abnormality of the one organ should be associated with an abnormality of the other, I should be glad to hear if any similar cases have been reported, or whether cases are on record of abnormalities of the kidney associated with an imperfectly descended testicle. It would also be interesting to know what the prognosis would be in this case should pregnancy occur at some future date.

A female child, aged 5 years, was admitted to the Royal West Sussex Hospital complaining of a tender swelling in the left groin. The mother stated that the child had had a rupture since birth, which for the past two years had been kept back by a truss. Eight hours before admission the child complained of pain in the left groin, and it was found that the swelling had become tender, and could not be pushed back. Five hours before admission the patient vomited partially digested food. The bowels had not been open for twenty-four hours.

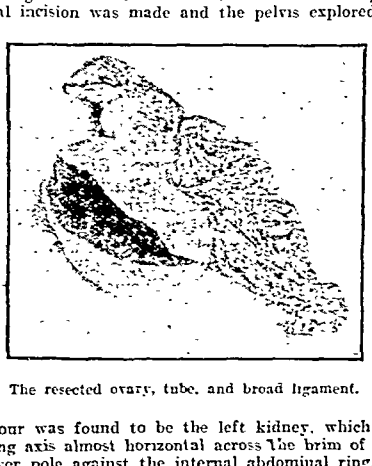
The patient, a well-built child, appeared to be in great pain. Temperature 97.6° F., pulse 140, respirations 24. Nothing abnormal was found on examination of the heart and lungs. The abdomen showed some rigidity over the whole of the left iliac fossa. In

Pyelograph taken when the patient was convalescent, showing the site of the left kidney.

the region of the central portion of the left inguinal canal was a firm, exquisitely tender, irreducible swelling, oval in shape, and about three-quarters of an inch in diameter. There was no impulse on crying. The skin over the swelling was hot, red, and oedematous. It was at once remarked that if only the patient had been a male the diagnosis would have been torsion of an imperfectly descended testicle. In the circumstances, however, the more obvious diagnosis of strangulated inguinal hernia was made.

Treatment.

One hour after admission, under general anaesthesia, an incision was made over the swelling. This was found to consist of a hernial sac containing blood-stained fluid and a strangulated gangrenous left ovary, tube, and broad ligament. Strangulation was found to be due to a torsion of the tube and broad ligaments, which were both markedly elongated. The gangrenous organs were then resected. Subsequently a smooth, rounded tumour of firm consistency was felt lying in the pelvis close to the internal abdominal ring. As this could not be identified a left paramedian suburnbilical incision was made and the pelvis explored.



The resected ovary, tube, and broad ligament.

The tumour was found to be the left kidney, which was lying with its long axis almost horizontal across the brim of the pelvis, and its lower pole against the internal abdominal ring. The left ureter was about two and a half inches in length. (This is well shown in the pyelogram taken when the child was convalescent.) In addition to its normal blood supply the kidney had an aberrant artery and vein communicating between its lower pole and the left common iliac vessels. The right kidney and ureter, the uterus, and right appendages were normal, though the uterus was displaced slightly to the left of the mid-line. Both wounds were then closed, and the child made an uneventful recovery.

Chichester. ARTHUR C. LIESCHING.

HAEMOPHILIA IN THE NEWBORN.

CASES of haemophilia in the newborn are sufficiently rare to warrant recording the following case.

A primipara, aged 23, was delivered after an uneventful pregnancy of an apparently healthy male child, weighing 8 lb. She suffered from a well-compensated mitral regurgitation (following rheumatic fever in childhood) and had been operated on for gastric ulcer.

I saw the child again six hours later and noticed it was tongue-tied. I divided the fraenum linguae, and there was no appreciable haemorrhage. The next morning I was told that the tongue had not stopped bleeding. I found blood still oozing from the region of the fraenum, and applied cotton-wool soaked in 1/1000 solution of adrenaline chloride, without success. Blood was also oozing from a slight abrasion at the tip of the nose, where I presume the infant had scratched himself. There were several ecchymoses on the back along the spine, and in the flexures of the arms and legs, presumably the parts exposed to pressure. There was a slight oozing from the base of the cord. Melaena was also present.

The child's hands were protected with gloves, and, as it was unable to suckle on account of the buccal haemorrhage, it was put on one-ounce feeds of cold barley water every three hours; two grains of calcium chloride was added to each feed. Milk was avoided so as not to stimulate intestinal haemorrhage. One minim of 1/1000 adrenaline chloride solution in a teaspoonful of water was given every hour for three hours, and then continued three-hourly. The child took these feeds well, but the oozing from the mouth, nose, and cord continued till the end of the fourth day.

After the haemorrhage had stopped for twelve hours the child was given a one-ounce feed of cow's milk and water at midday of the fifth day, and another at 3 p.m. I was hastily summoned at 4.30 p.m., when I found the child bleeding profusely from the base of the cord, which had not yet separated. The child was cold, the respirations were shallow, and the pulse was weak. I packed the wound with horse serum, and injected 10 c.cm. subcutaneously. The bleeding stopped in about five minutes. The child was wrapped in blankets, and hot-water bottles were placed in the cot. At 9 p.m. the child was quite warm, and there was no haemorrhage. Another injection of 10 c.cm. normal horse serum was given, and adrenaline by mouth continued. At 5.30 a.m. on the sixth day the child died. There was no necropsy.

I cannot trace any definite family history of haemophilia, but I was told that the mother's grandmother on the paternal side had had twin sons who died at birth of some "blood disease."

London, S.W.11. J. L. BLONSTEIN, M.R.C.S., L.R.C.P.

Reports of Societies.

BRITISH PAEDIATRICS: PAST, PRESENT, AND FUTURE.

AT the annual meeting of the Section of Disease in Children (Royal Society of Medicine), on May 24th, Dr. F. JOHN POYNTON delivered his address from the chair, taking for his subject some phases in paediatrics as viewed by a general physician.

The earlier part of Dr. Poynton's address was occupied with some interesting reminiscences of consulting physicians and surgeons to the Great Ormond Street Hospital with whom he had been associated—Sir Thomas Barlow, the late David Bridge Lees, the late Edmund Owen, and others. In an earlier generation, from 1852 to 1862, Sir William Jenner was physician to that hospital. Dr. Poynton, who had always thought that Jenner's portrait showed a formidable personality, once asked Sir Thomas Barlow how Jenner managed children, and he was interested in the reply that, when Jenner was among sick children, all that was good and benign in his nature seemed to radiate from him, and he was at his very best. Among surgeons whom he had known, Edmund Owen (formerly Chairman of Council of the British Medical Association) had always remained in his memory as the greatest teacher of students he had ever met. It was possible that his direct and forceful methods would prove too terrifying for the modern student, but no one could drive essential and practical instruction into the head with more incisiveness. Three men among others to whom Dr. Poynton was house-surgeon, and to whom he was deeply indebted, were Sir Thomas Barlow, Dr. Lees, and Sir Archibald Garrod. To Lees he owed more than he could say. He always thought of Lees as of a Roman gladiator combating with straightforward weapons an antagonist with a net and short dagger. Lees hurled his clear mathematical intelligence upon his foe—disease—but sometimes he was ensnared by the other with devious strategy. Another consulting physician at Great Ormond Street of whom he had memories was Walter B. Cheadle, and here he showed the Section some interesting photographs illustrating Cheadle's historic journey with Viscount Milton across North-West America in the sixties, when not a few privations were endured. He remembered being shown by Cheadle the belt he wore at that time, with the holes which he drew in one by one. Cheadle was the first to define infantile scurvy, which he ascribed to artificial foods containing no antiscorbutic element.

In those earlier days, in children's diseases, there was a great field in which to work. Surgical opportunities were perhaps not so striking as medical ones, but disease in all its complications was to be seen in a children's hospital. The amount of special knowledge which was simmering in the children's hospitals in the days he was recalling, but which had not quite reached articulate expression, was also remarkable. Those days were now disappearing, and the position of the man interested in children's diseases rather resembled that of a collector who had at first come upon many rare specimens, but now was continually meeting with duplicates, and had great difficulty in usefully extending his collection. In the particular Section he was addressing Dr. Poynton felt that there was an increasing tendency to demand cases of extreme rarity to stimulate a jaded appetite. It was not true to say that in the old days research was not in evidence. It was easy enough to underrate the value and originality of the work of the old clinicians because it was done in hospital wards and not in laboratories, and because often it only directed a line of investigation, and did not explain the facts which it had extracted from the tangled skein of human disease. In these days there was often a tendency to suppose that research—a term woefully misused—was the prerogative of the laboratory. Nevertheless, as purely clinical research diminished in its scope, laboratory research became more necessary. This stage was now being reached, and its developments were to be seen in all directions. Much of the present order of research demanded highly skilled training, with the result, as he saw it, that specialism in children's diseases would continue to develop, and the general physician would hesitate to attempt researches which were so prolonged and special. It was interesting to speculate whether the trend of specialism would stop at its present phase or whether, fifty years hence, if he could look in at the Section for the Study of Disease in Children, he would find children's specialists in cardiac disease, in nervous disease, in dietetic disorders, and so forth. If this development should take place it would mean a great waste of intelligence, for brilliant minds would be spending themselves on small details and within narrow limits, and missing many interactions and co-ordinations. One might even foresee a still further stage in medical thought when the specialist to be called for would be one who had a general knowledge of human disease. Dr. Poynton said that he himself belonged to a closing chapter in the history of paediatrics. The general physician with a special interest in children was disappearing. The scope of the subject had become so great that the expert was finding that all attention must be devoted to this one subject. The public demanded a children's specialist, and, the first necessity of life being to make a living, there was a steady pressure in that direction. The establishment of paediatrics had been one of the great steps in the history of medicine. Although it seemed an inappropriate observation from one who was the president of the Section, he could not help regretting the disappearance of the Society for the Study of Disease in Children, which was its forerunner. The change was inevitable, but some personal touch was lacking in the new order. Looking back over the years spent among sick children, he did not think that to-day men worked harder than their predecessors, or with more enthusiasm; but there had been a distinct improvement in the social condition of the poor, and the terrible cases formerly seen were by no means so frequent. The work to-day was more accurate and detailed, the resources were greater, but the breadth of experience was in danger of disappearing.

Turning from this retrospection to the immediate future, Dr. Poynton said that changes were taking place which

would greatly influence the study of paediatrics. One outstanding event had been the establishment of the Ministry of Health, and no branch of medicine would feel the influence of the Ministry more surely than this. The Ministry, of course, was more intent upon prevention than upon the intricate study of disease, but inevitably the organization for the care of children must more and more pass under the control of the Ministry, while the study of disease remained the province of the hospitals, and between the two there must be an active intermediary, maintaining touch with the Ministry on the one hand, and with the hospitals on the other. On many sides the children's hospitals were already feeling the difficulties which were developing. There were special provisions for fever cases, for surgical tuberculosis, for syphilis, for many other diseases affecting children. He was in no way criticizing this inevitable development, but the result was to bring about a certain lack of continuity in the treatment of the child as an individual. Another, perhaps somewhat sordid, consideration came in. As the state extended its activities, there would be a standard of payment for State medical officers on the one hand, whereas on the other the honorary officers of hospitals received no remuneration. Little by little the able physician or surgeon would become doubtful whether the liberty of action of the honorary officer, which the older men at all events knew how to value, was not being gained at too great a price. But one essential factor in the whole position was that there were in this country two great systems, one the Ministry of Health, where preventive organization was paramount, and the other the great hospitals whose success was based on very many years of experience and teaching. The hospital organization possessed the precious asset of a system of education based on the experience of years, which gave remarkable freedom of thought and action, and opportunities for doing the best kind of work to those who were bent on the service of medical science. The blending of these two great features, the hospitals and the Ministry, was the problem of the future, so that each, while maintaining its proper sphere, might help the other. Dr. Poynton also sketched future possibilities in the work of the Section.

In proposing a vote of thanks Dr. J. D. ROLLESTON drew attention to the official printed announcement of the address, which bore the American spelling "pediatrics." He hoped that this would not receive the sanction of the Royal Society of Medicine, especially as the *British Medical Journal* now adopted the proper form, with the diphthong.

THE DICK TEST IN PUERPERAL FEVER AND PYREXIA.

AT a meeting of the Section of Epidemiology and State Medicine of the Royal Society of Medicine on May 24th, with Dr. S. MONCKTON COPEMAN in the chair, Dr. ALEXANDER JOE read a communication on puerperal fever and pyrexia, and related particulars of a series of cases coming under his observation at the North-Western (M.A.B.) Hospital.

Dr. Joe placed his 219 cases into six categories as follows: (1) uterine infections; (2) pelvic or general peritonitis; (3) pelvic cellulitis; (4) general infections of the blood stream; (5) infections of the urinary tract; (6) miscellaneous, including mental disturbances, constipation, breast troubles, and other conditions consequent on the puerperal state. The detailed classification was as follows:

Category.	Number of Cases.	Deaths.	Recovered Cases.	
			Average duration of pyrexia in days.	Average number of days in hospital.
1	71	Nil	4·5	20.5
2	47	17	16.8	37.1
3	11	1	10·1	46.2
4	20	15	26.5	74·0
5	12	Nil	13.5	32·9
6	58	1	(Not estimated)	

Of the 47 cases in Class (2) (peritonitis), 23 had pelvic peritonitis and 24 the general condition; all the deaths were among the latter. The 20 cases in Class (4) (general infections) included 12 septicaemias (10 deaths) and 8 pyaemias (5 deaths). Of the 32 puerperal deaths, 7 were the result of septic conditions following upon abortion, directly attributable, save for an infinitesimal fraction, to instrumental intervention; this was a conservative estimate. Of the remaining 25 deaths, 11 had occurred in primiparae and 13 in multiparae (one was uncertain). Among the primiparae, 8 of the deaths followed instrumental labours, with severe laceration in 5; in the three unaided labours there had been bad tearing of the birth canal in one, slight tearing in another, and the third, undamaged, had retained placenta. Normal labours had taken place in 9 of the multiparae who died, and instrumental labours in 4. He thought that the group of multiparae might be regarded as a sort of control upon the group of primiparae, and these figures were interesting from the point of view of trauma as a factor in the production of sepsis. Dr. Joe then gave an analysis of the 116 recovered cases in the first four categories of puerperal infections as follows:

Category:	1.	2.	3.	4.
Number of cases	71	30	10	5
Vaginal examination before labour:				
None	21	13	5	2
Uncertain	4	3	—	1
Labour:				
Instrumental	11	5	3	3
Normal	41	21	6	—
Result of Pregnancy:				
Healthy child	47	26	9	4
Dead child	4	—	—	—
Abortion	19	3	1	1
Unknown	1	1	—	—

Dr. Joe went on to describe how, following upon the work of Dr. Burt-White with regard to the Dick test and streptococcal infection in the puerperium, he had made a number of Dick tests in the puerperal fever ward at the North-Western Hospital. Patients were tested on admission by intracutaneous injections of Dick toxin. Altogether, 103 practically consecutive cases of puerperal sepsis were taken, of which number 26 were found to be positive and 77 negative to a 1 in 1,000 dilution; 39 of the 103 were positive to a 1 in 200 dilution. The percentage of positive reactors in this series of puerperal infections was almost identical with the figure obtained by Dr. Burt-White. Out of these 103 cases he had taken 22 from which he had isolated the haemolytic streptococcus; of this number 7 were Dick-positive and 15 Dick-negative. The analysis was as follows:

Infection.	No. of Cases.	Dick-negative.	Dick-positive.
Local uterine infection	12	8	4
Pelvic peritonitis	4	2	2
General peritonitis	2	1	1
Blood infection (septicaemia 3, pyaemia 1)	4	4	—

It would appear, therefore, that invasion by the haemolytic streptococcus was not restricted to Dick-positive cases.

The CHAIRMAN said that an enormous amount of work from the bacteriological and epidemiological point of view had been undertaken recently on this subject, more especially by his colleagues in the Ministry of Health and in various associated laboratories. The general outcome had seemed to be that there was only one specific type of organism concerned in all the infections, and therefore it was all the more important to learn from Dr. Joe that apparently this had little bearing on the question of treatment in these puerperal fevers and puerperal pyrexias. With regard to treatment, the speaker referred to a book written by Edward Copeman of Norwich in 1860, and entitled *Illustrations of Puerperal Fever*. The author, who was a well-known gynaecologist, drew attention to a method of treating puerperal fever which he ascribed to a Dr. Brennan in Dublin about 1814. It consisted in the use of turpentine internally as a medicine or an enema, or externally as stupes; he reported a number of cases in which certainly the effects appeared to have been exceedingly

good. Dr. Copeman declared that seven out of his last eight patients recovered, and as he was strictly a consultant—one of the first of the provincial consultants, who rigidly refused to have anything to do with patients who had not come to him in the ordinary way of consultation—the cases must have been pretty bad ones.

Dr. FOORD CAIGER remarked that it was extremely disappointing to realize what little benefit seemed to have resulted from the amount of work done clinically and in the laboratory in connexion with puerperal sepsis. He remembered that when he was resident accoucheur at St. Thomas's Hospital, forty years ago, he had had 600 confinements and lost *only one*, while the number of cases of puerperal fever was very small. At a recent conference at Zürich he had been interested to find that in Switzerland they did not seem to be any more successful than in this country, but they seemed to adopt a more passive attitude. The great principle there appeared to be to wait until the result of the blood examination was apparent, and then to begin to treat. It never seemed to occur to them to put the unfortunate patient into a position which might be favourable to recovery to start with, and then to call upon the bacteriological expert to make his report. As regards the treatment they did employ in Switzerland, the great thing seemed to be to safeguard the patient against thrombosis, and to that end she was subjected to gymnastics, even at a very grave stage of the illness.

Dr. LEONARD COLEBROOK congratulated Dr. Joe on his careful Dick-testing work. It did not surprise him to hear the result, because he had gathered that from other parts of the country similar results were forthcoming; it seemed as if the idea that a Dick test could be regarded in the same light as the Schick test in diphtheria would have to be abandoned. He concluded that it was necessary to look to treatment primarily of the bacterial invasion, and that no satisfactory cure for this would be forthcoming in the immediate future. Not enough was yet known of the factors governing the invasion of the *streptococcus*.

Mr. HAROLD B. BUTLER referred to the possibility of faecal *contamination*. It appeared from the researches of Hurst that 4 per cent. of people had achlorhydria, and did not sterilize the food in the stomach, so that organisms from the tonsil or elsewhere could be found in the faeces. Might it not be, therefore, that infections from the stool explained a number of these cases?

Dr. PHYLLIS DIXON asked whether the cases dealt with by Dr. Joe had been in any way selected, and Dr. J. A. H. BRINCKER whether, in addition to the testing for *Streptococcus haemolyticus*, work had been done on other types of organisms. Dr. JOE, in reply, said that the cases received were not selected in any way. It was evident that in the vast majority of these cases the *Streptococcus haemolyticus* was the primary factor. He agreed that the hope for success in treatment lay in some method which would prevent the pyogenic manifestations of the streptococcus. The only thing which he had seen so far to have any beneficial effect was, in certain cases with general peritonitis, to operate and *drain* the peritoneal cavity; here there had been one or two successes.

ACUTE ARSENICAL POISONING.

AT a meeting of the Medico-Legal Society, on May 23rd, a discussion took place on the subject of acute arsenical poisoning. It was opened by Sir WILLIAM WILLCOX, who also occupied the chair.

Sir William Willcox, after pointing out that it was an unwritten law of the society that no reference should be made to cases which were *sub judice*, said that he proposed to confine himself to recent advances in the technique of investigation and to certain recent cases the public proceedings in which were concluded. There had been during the last few years striking advances in chemical analysis and in the procedure of *post-mortem* examination with a view to the discovery of arsenic. From the cloudy swelling and degenerative changes in the liver and other organs and the condition of the gastro-intestinal tract and of the blood, it was almost possible to say that the case was one of acute *arsenical poisoning* without calling for the discovery of the arsenic. Much experience of the action of arsenic had been derived from the employment of the drug therapeutically in disease. Organic compounds of arsenic, the best known of which was salvarsan, one of the arsenobenzol derivatives, had been used in treatment to an enormous extent. Not long ago the speaker was called to a serious case of rat-bite fever with recurring symptoms extending over a long period; rat-bite fever was caused by an organism very like that which produced syphilis, and the patient was cured after one dose of salvarsan administered intravenously. Sometimes these therapeutic substances had a toxic action. One patient died with cirrhosis of the liver after eleven doses of salvarsan. But all this work had helped greatly in adding to the knowledge of the action of arsenic in the body. Arsenic in minute amounts was really one of the body's normal constituents. It occurred also in certain foods. In 1900, there was an epidemic of arsenical poisoning traced to the drinking of beer in the brewing of which there had been used a commercial glucose made from starch by treatment with sulphuric acid which contained appreciable amounts of arsenic. As a result of the Government inquiry which followed it was found that a number of foodstuffs contained arsenic, and the departmental committee laid down certain limits which must not be exceeded in foodstuffs offered to the public. Since that time there had been very few cases of arsenical poisoning from foods. About ten years ago a few cases (none of them, he thought, fatal) occurred as a result of drinking some soluble cocoa treated with potassium carbonate containing some arsenic which had been overlooked. It had recently been shown that certain kinds of fish contained appreciable quantities of arsenic; flatfish such as soles and plaice contained up to 0.1 mg. in 100 grams, probably not in the form of the arsenious acid, As_2O_3, which was used by persons with homicidal tendencies, but nevertheless absorbed by those who partook of *this diet*, and excreted in the urine. Crustaceans, such as lobsters and shrimps, contained relatively large amounts—from 20 to 40 parts per million, which was far above the limit (1.4 parts per million) officially permitted in foodstuffs. In the recent Llewellyn case, which created some stir in Wales, the deceased person, who was found to have *in the heart* and in the liver 0.4 part per *million*, and in the kidney 0.6 part, had been partial to plaice and other fish, and this long-continued diet was sufficient explanation of the arsenical traces which were found, with the result that the verdict was "natural causes." Arsenic had been from time immemorial the principal poison chosen by homicidal persons, for the reason that it was almost tasteless, was toxic in small amounts, and produced clinical symptoms which few medical men could distinguish from those of natural disease. Its description as an irritant poison was unfortunate; it was true that it had irritating effects, but it was really a tissue poison, affecting all the organs of the body, so that persons suffering from arsenical poisoning might die of heart failure, of toxic jaundice, or of badly damaged kidneys. Those who did not die might be permanently damaged. Sir William Willcox then discussed the familiar circumstances of the Pace case tried at Gloucester assizes in 1928. The deceased had had at least *five* fatal doses of arsenic. Enormous quantities of arsenic were found in the body—altogether 9.4 *grains in the* organs examined. Pace was a sheep-farmer, and it was probable that the arsenic was derived *from* sheep-dip.

Professor I. WALKER HALL then took up the story and described the properties and action of sheep-dip. The substance could be obtained easily by anyone who was known to have the care of sheep, and was in the form of a yellow granular powder containing fragments of arsenic dioxide, sodium carbonate, and coarsely ground sulphur. Each packet of sheep-dip contained about 1,400 minimum fatal doses. It was prepared in solution, and in making or handling the solution there was really very little danger. The idea of the cutaneous absorption of arsenic still remained a bogy which it was almost impossible to lay. The speaker described how he had experimented on himself. He rubbed a fatal dose of arsenic thoroughly over the extensor surface of his hand, letting it stay there for thirty minutes; then he soaked the hand in water and allowed it to dry in the air. He experienced no local irritation of the skin, no local symptoms of any kind, and the urine showed no extraordinary quantity of arsenic. He repeated the experiment, with the same result. He

next undertook certain experiments to determine the effect of single and repeated doses of sheep-dip solution introduced into the stomach of the rabbit, the animals being killed after twelve or twenty-four hours. Practically the whole of the fatal dose of arsenic in a soluble form could pass into the tissues of a rabbit in twelve hours. Professor Walker Hall also showed photographs illustrating the action of the material upon the stomach, the intestines, the liver, and the heart. The heart muscle at first showed striations, and eventually practical disintegration; and at a very early stage after the administration of arsenic from sheep-dip to rabbits one could discern definite changes in the blood vessels.

Dr. J. H. RYFFEL referred to one form of acute or chronic arsenical poisoning not previously mentioned—namely, that produced by arseniuretted hydrogen, which would appear to cause haemolysis of the blood. In the early days of submarines there were cases of such poisoning; the sulphuric acid of the accumulators contained arsenic, and in the charging of the accumulators arseniuretted hydrogen was evolved in small doses. A special feature of this arseniuretted hydrogen poisoning was jaundice, to which there was always a tendency in poisoning by arsenic. The action of arsenic on the liver in causing necrosis of the liver cells was also very remarkable. This could be demonstrated in salvarsan jaundice, where a person had been overdosed with salvarsan or had some idiosyncrasy towards the drug. Many attempts had been made at devising tests for the function of the liver. One of the great drawbacks in such tests was the largeness of the organ and the difficulty of demonstrating deficiency in function. If the hepatic deficiency was sufficiently marked, however, the levulose test met the case quite well.

Mr. EDWARD HINKS gave a technical description of the chemical analysis for arsenic, and discussed the merits of Reinsch's test, the Marsh-Bezelius test, and others. Most of the developments in the last few years had taken place in connexion with the electrolytic modification of the Marsh test, in which recently a mercury cathode had been used with great success. He exhibited a set of arsenic "mirrors" thus obtained. For toxicological purposes the Marsh electrolytic test was the safest and most satisfactory. These highly refined methods, however, owing to their very delicacy, were subject to a serious percentage of error, and where the concentration of arsenic was at all high it was preferable to use the ordinary mineral graphometric method, with which, given higher quantities, the margin of error was nothing like *plus* or *minus* 10 per cent., as it was with the more refined methods. He was still of opinion that the detection or determination of arsenic in the human tissues remained—to borrow a phrase from surgery—a "major operation." In reply to a question, he said that there was no spectroscopic test available.

The hour did not permit of any further discussion, but one or two questions on technical details were answered by Sir WILLIAM WILLCOX and Professor WALKER HALL. One of these related to the presence in apples of arsenic derived from the spray used on the trees before the fruit was formed. Cases of this kind were known, though not, Sir William Willcox thought, in home-grown or even in Dominion produce.

THE USES OF SCARLET FEVER ANTITOXIN.

AT the annual meeting of the Fever Hospital Medical Service Group of the Society of Medical Officers of Health, held at the House of the Society on May 24th with Dr. E. H. R. HARRIES in the chair, a short discussion took place on the uses of scarlet fever antitoxin.

Dr. W. MAIR MACFARLANE of the City Hospital, Birmingham, brought forward analyses of more than 800 cases of indubitable scarlet fever; some of the patients had had serum treatment and others had not. Among the total cases six deaths occurred (a case mortality of 0.7 per cent.), but one patient was moribund on admission and another had diabetes. Only seven of the cases could be brought within the category of septic scarlet fever, and all the patients recovered except the one who was moribund. Cases were selected for serum treatment on the ground of clinical suitability; among those so treated the incidence of complications was 19.2 per cent., and among those not so treated it was 25.2 per cent. The only really significant difference between the two categories appeared on the first and second days of the disease, when the percentage of complications among the serum-treated was about 18, and among those not treated by serum 31 per cent. In 74 patients who were severely ill, though without sepsis, and all of whom were treated with serum, there was uneventful recovery in all except 11, who had complications. Of the patients treated by serum 1.5 per cent. relapsed, as did 2.3 per cent. of those not so treated. The speaker gave some account of commencing cases which had aborted after the prophylactic use of 5 or 10 c.cm. of serum. With regard to serum reactions, out of 325 cases, 93 showed reactions and 232 (71.4 per cent.) no reactions. The majority of the reactions were quite trifling, but in 23 instances there was an intense general rash, and in 10 severe multiple symptoms.

Dr. H. S. BANKS of the Isolation Hospital, Leicester, said that last year he had to deal with a rather considerable epidemic of scarlet fever, which taxed the hospital accommodation to the utmost. He used antitoxin intravenously, and found it so successful and convenient that he now used it in this manner as a routine for definite cases of scarlet fever, with very few exceptions. He had so treated 486 cases during the last twelve months, giving to children from 5 to 10 c.cm. of the (Parke Davis) serum, and to adults from 10 to 20 c.cm., according to the severity of the disease. As to the immediate serum reaction, about 60 per cent. of the patients had rigor and hyperpyrexia lasting for about half an hour, but he had seen no fatality directly resulting. In the acute stage quite dramatic results might be claimed for the serum. There had not been a single case of the more important complications of scarlet fever—namely, otitis media, acute nephritis, and acute arthritis. The complications were limited to fourteen trivial septic occurrences, including adenitis and nasal discharge, and also one case of intermittent albuminuria, which was probably functional. Serum rashes appeared to be of smaller incidence than with intramuscular injection. In 300 cases, extending over the last seven months, the average stay in hospital for the cases so treated had been sixteen days. Adults did so well that they were discharged after, on the average, eight or nine days. Desquamation was generally absent or trifling—a powdering of the hands. He had a system whereby the patients reported at the public health office in the city a week or so after their discharge; they came willingly, appearing to regard this as a sort of clearing-off certificate. Return cases had worked out at 1.7 per cent. The great advantage of the treatment was that it enabled half the ward accommodation formerly devoted to scarlet fever to be devoted to other purposes. The cost of serum treatment worked out at an average of 15s. per case.

Dr. ALEXANDER JOE (North-Western Hospital, London) confined his remarks to prophylaxis; the doses of serum ordinarily recommended were 2.5 and 5 c.cm. This might well apply to the fairly large group of cases which would be Dick-negative and resistant to the disease, but, in his experience, when a case of scarlet fever had occurred in a ward, if the exposed population gave a reaction under 20 mm. in diameter, 5 c.cm. were customarily given, and above that, 10 c.cm. In an adult case he thought that, to be absolutely certain of results, 10 c.cm. should be given. To be on the safe side, in all cases at least 5 c.cm. should be given, and, unless there was going to be careful control by the Dick reaction, this should be exceeded up to 10 c.cm.

The CHAIRMAN said that he was rather hesitant about the short period which Dr. Banks gave for residence in hospital; he himself insisted on twenty-eight days in hospital for the uncomplicated case. He was also a little dubious about a dose which induced a rigor, and, altogether, in mild cases of scarlet fever he was not prepared to introduce antitoxin intravenously.

Dr. R. A. O'BRIEN pointed out some puzzling features which emerged from a review of the literature of the subject. There were instances of patients giving a severe reaction to a minute amount of serum, and later on being given serum without any reaction at all. He also spoke of the difficulty, in intravenous administration, of ensuring that the serum actually entered the vein, and exactly at the body temperature; one or two physiologists had said that this was of importance in relation to the subsequent reactions.

TUBERCULOSIS FROM A SURGICAL STANDPOINT.

AT a meeting of the Kidderminster Medical Society, held on May 10th, Mr. J. LIONEL STRETTON read a paper entitled "Tuberculosis viewed from a surgical standpoint."

Mr. Stretton said that if it was true, as had been stated, that tuberculosis was introduced into the body through the lymphatic system, the surgeon should be interested in its treatment and in its prevention. If phthisis was the end-result of lymphatic infection, it seemed obvious that the best way to prevent it was to guard the lymphatic system, and to treat any infection of that system at the earliest possible moment. There was no proof that tuberculosis of the respiratory tract had ever been contracted primarily by the direct inhalation of tubercle bacilli. Experienced veterinary surgeons knew that lung tuberculosis in cattle was secondary to tuberculosis in the mesenteric glands; probably the same was true of human beings. It was said that inoculation of a wound with tubercle bacilli, or their accidental entry through a skin abrasion, led to a local lesion only, for the skin constituted the chief tissue of defence. He knew of no proof that human beings had contracted phthisis as the result of skin infection with human or bovine tubercle bacilli. Tuberculous meningitis, he continued, was commonly due to the bovine type of organism, which supported the view that the disease was secondary to infection of the abdominal lymphatics, the infecting organism being usually of the bovine type. The human type of bacillus occasionally found in the abdominal lymphatics was probably introduced with food which had been handled by consumptives, their hands being hardly ever free from tubercle bacilli. This might be the reason why the offspring of tuberculous parents more often developed the disease than did those produced by healthy stock. Some authorities were of opinion that human bodies might possess a tendency to develop tuberculous disease, and, furthermore, that this tendency was hereditary. At present this was a debatable point. The fatty covering of the bacilli enabled them to resist the digestive action of the gastric juice, so that they had no difficulty in reaching the intestinal tract. The most common situations of the infected glands were the mesentery and the neck. The lecturer believed that infection was more frequent in the former, but being far more difficult to diagnose it was often overlooked. McFadden (*British Medical Journal*, December 24th, 1927, p. 1174) had stated that of 6,000 to 7,000 cases of mesenteric lymphadenitis only 45 had been correctly diagnosed. During the past ten years Mr. Stretton had operated upon 57 children with tuberculous glands of the neck and 84 with tuberculous glands of the mesentery. These figures supported the view that infection of the mesenteric glands was commoner than infection of the glands of the neck. Furthermore, enlarged cervical glands, or evidence of their previous existence, were seldom found in patients suffering from phthisis, so if it was true that phthisis was secondary to lymphatic infection almost certainly the lymphatics of the mesentery were responsible.

It had been suggested that enlarged glands in the mesentery were tuberculous in only a few cases. An alternative suggestion was that their enlargement was generally due to septic infection. If this were true the symptoms would be more acute and suppuration would not be uncommon. Why, moreover, were enlarged glands so seldom found in the mesentery in cases of acute appendicitis? It was not always possible from a microscopical examination to state that a lymphatic gland was tuberculous, but when the glands were caseous everyone would admit that they were tuberculous. Caseous glands, said the lecturer, were present in more than half of the children he had operated upon, and in his opinion it would be wise to regard all enlarged mesenteric glands as tuberculous, unless it could be proved that the infection was due to another organism. To lessen tuberculosis the lymphatic system had to be watched, and primarily the lymphatic system of the mesentery. The bacilli were supposed to gain entrance to the lymphatics of the mesentery through glands in the intestine, especially in the distal portion of the ileum. He suggested that the chief portal of entry was the appendix. In the patients he operated upon he found that the appendix was often old adhesions in its vicinity. Its removal led to immediate improvement in health. The diagnosis of these cases was difficult, and the symptoms were often indefinite. There was usually a long history of abdominal pains, irregular action of the bowels—which sometimes were constipated, at others relaxed—variable appetite, and usually some loss of flesh. Vomiting was not common, and the temperature did not usually rise above 101° F. The abdomen was often distended; it moved freely, and as a rule was not rigid or tender. The enlarged glands could usually be felt by a practised hand, but this was not easy. When the abdomen was opened some free fluid was usually present, but not enough to have been diagnosed before the operation. It was his custom to remove the appendix, and sometimes a gland too, for examination by the pathologist, but it would be unwise, if not impossible, to remove all the glands. In ten years he had operated upon 84 children, of ages varying from 9 months (one) to 11 years. The results, so far as could be ascertained, were as follows: 7 had died, 2 from subsequent tuberculosis; 39 were well; 3 were weakly, but had no definite tuberculosis; 15 could not be traced, and 20, operated upon within the last six months, were so far satisfactory.

Dealing with the prevention of tuberculosis, Mr. Stretton said that whereas many efforts had been made to secure a food supply free from tubercle bacilli, the persons engaged in the distribution of food had been overlooked. The only means of eliminating tuberculosis were to enact that no sufferer from tuberculosis should be allowed to assist in the food distribution of the country, and that all persons who did so assist should be periodically examined. He felt confident that in the future it was the lymphatic system that would be watched, and primarily the lymphatics of the abdomen.

AT a meeting of the London Jewish Hospital Medical Society, held on May 16th, with Dr. A. GOODMAN LEVY in the chair, discussions took place on the acute abdomen and on the acute ear. Mr. E. G. SLESINGER stressed the heavy mortality, still running into thousands every year, for which the acute abdomen was responsible. These deaths were partly due to technical difficulties, partly to some circumstances outside professional control, and several other factors, but mainly to delayed surgical intervention. Masterly inactivity finds no place in the treatment of the acute abdomen, except when applied by a master under ideal conditions and supervision; in other circumstances it is a policy which swells the mortality returns. In no other branch of medical practice was vaccillation so disastrous. Mr. M. SOURASKY, speaking on the acute ear, recalled the fact that 1,200 deaths are reported annually from this cause. But these were the dramatic consequences of the poor treatment of the acute ear. The less dramatic consequences were the people afflicted with deafness, unbearable tinnitus, and chronic ill health, with danger to life from everlastingly discharging ears. Inefficient treatment of the acute ear maimed rather than killed. The deaths and the chronic sequelae were the result of the cavalier treatment usually accorded to the acute ear conditions; they represented nothing less than collective professional malpraxis. Nothing was less difficult and uncertain than the treatment of the chronic ear conditions and their acute complications, and nothing easier than the treatment of the source of these troubles during its acute stage. Acute otitis media treated on rational lines—catheterization in the catarrhal variety, and paracentesis in the purulent type—subsided quickly, and the formidable array of sequelae were thus avoided. Should mastoid tenderness develop a free paracentesis would probably cure the condition, but in frank mastoid infection antrotomy would be necessary. Any acute otitis media which kept on discharging, whether through a spontaneous or a surgical opening of the drum, for more than four weeks after appropriate treatment ought to have a mastoid operation. Only thus could the appalling cases of chronically discharging ears, with all their possible complications, be avoided. It was much easier to prevent the establishment of chronic infection throughout the territory of the middle ear than to eradicate it. The great frequency of incurable chronic ear conditions must not be ascribed to the otologist; it was rather the result of the treatment by the profession as a whole of the acute ear conditions as if they were a nuisance, and the failure of most hospitals to supply the trouble, and the failure of most hospitals to supply the surgeons with anything but a niggardly number of beds.

Reviews.

OESOPHAGEAL OBSTRUCTION.

UNTIL a few years ago affections of the oesophagus remained somewhat of a barren theme, and it is only with the wider development of endoscopy in recent times that the subject has attracted specialist workers who have advanced our knowledge materially and embodied their results in various monographs and textbooks. A recent work[1] from the pen of a general surgeon, Mr. LAWRENCE ABEL, views the subject from another angle, and it appears at an opportune time. Based on the Jacksonian Prize Essay of the Royal College of Surgeons for 1924, which has been extensively revised, largely rewritten, and added to, it contains as well an account of a considerable amount of experimental work upon animals with reference to the surgery of the thoracic oesophagus.

Prefacing his survey by a detailed description of the anatomy of the parts, the author lays stress on the fact that the gullet is an extremely delicate organ liable to be ruptured by any sudden or injudicious stretching, as with an instrument. In the chapter on bacteriology he emphasizes the significance of the large numbers of micro-organisms in the upper food tract and the presence of certain of the more virulent which live only when teeth, and especially carious teeth, are *in situ*, a consideration which renders imperative a scrupulous toilet of the mouth before operations lower down are undertaken. For the purposes of diagnosis, whilst radiography in the right oblique position is advocated, the value or even necessity of supplementing it by x-ray films taken in other planes, notably when dealing with foreign bodies, might well have been insisted on. The author favours a large-bore oesophagoscope with proximal or distal illumination and the patient in the dorsal recumbent position.

Considerable detail is devoted to the important subject of spasm. At the upper end of the gullet the author regards it as due to tonic contraction of the cricopharyngeus. At the lower end a true sphincter is held to exist in the oesophageal wall at the level of the diaphragm, and here spasm occurs; and he proceeds to claim that hypertonicity or spasm produces local passive congestion resulting in fibrinous induration, such as forms the "pecten band" in the anal canal, often a precursor of rectal cancer. This fibrinous deposit at the opening of the gullet by limiting its expansibility gives rise to painless dysphagia, which may terminate in hypopharyngeal malignant disease. A similar change occurs at the cardiac sphincter in cases of cardiospasm. The account of upper spasm with its syndrome of dysphagia and anaemia is, on the whole, disappointing, and omits the important fact that it is confined to the female sex. On the other hand, cardiospasm, which is regarded as a spasm of the cardiac sphincter, receives full discussion as to its symptoms and clinical examination, and its treatment by dilatation with the rubber bag is warmly endorsed from the author's experience.

In cancer of the oesophagus Mr. Abel regards the lack of success as due to late diagnosis, and urges recognition of its earliest symptoms and a direct examination on the first signs of discomfort. As a palliative measure moderately early gastrostomy is advised. Intubation, radium, diathermy, and deep x-ray therapy are fully discussed and their limitations defined. But it is to the radical removal of the disease that one of the most valuable and suggestive chapters is devoted. The author holds that in the absence of any contraindication—for example, metastases or extreme emaciation—it ought to be attempted, and this applies not only to the cervical oesophagus, but also to the thoracic part. As the disease long remains localized and glandular metastases are the exception early recognition is important, and we are on promising ground in enlisting the help of the general practitioner.

The book has good illustrations, and without pretending to be exhaustive may claim a cordial welcome for more than one reason. The general practitioner will find an admirable account of the subject, which cannot fail to awaken an interest where his co-operation is urgently needed, and, on the other hand, the specialist will derive material for thought as to the possibility of help from general surgery in his most pressing problems.

[1] *Oesophageal Obstruction: Its Pathology, Diagnosis, and Treatment.* By A. Lawrence Abel, M.S.Lond., F.R.C.S.Eng. Oxford Medical Publications. London: Milford, Oxford University Press. 1929. (Sup. roy. 8vo, pp. ix + 234; 152 figures, 2 plates. 30s. net.)

CARDIO-VASCULAR DISEASE.

A MORE complete list of references, old and new, to the literature of the subject than that included in the work on diseases of the heart and the vessels,[2] by Professor ERNST EDENS, does not exist, and the author has thus rendered his book indispensable to students of the circulation; there is scarcely any branch of cardio-vascular disease the position of which is not clearly defined in terms of the latest publications of the subject. This very universality of treatment has its disadvantage that many of the older ideas about valvular heart disease are reproduced in the text by the side of newer considerations, and the general reader may not understand that this branch of cardiology is now viewed from another angle. It is a surprise to find that a writer who boldly, and probably rightly, bases his prognosis in angina pectoris on the response to effort has not with equal courage discarded these conceptions of the influence of valve lesions on the structural and functional future of individual chambers of the heart which had their inception almost exactly one hundred years ago, and have in the course of the past twenty-five years been found unreliable. For we do not know exactly what influence a slight stricture of the mitral orifice, for example, has on the heart. Nature's experiments are not designed to solve our academic problems, which are created largely, as Bergson pointed out, by man as *Homo faber*, who has no alternative (owing to the nature of his intellect) to dividing the continuous, and to dealing individually with the parts separated off, it may be, in a way which admits of no recombination.

This book is beautifully produced on excellent paper and contains many diagrams. There are 750 pages of text and nearly 250 pages of references to the literature; an index of authors is appended. The opening chapters on the history and on the development, anatomy, and physiology of the organs of the circulation are followed by a most comprehensive chapter on the methods of investigating the functions of these organs. The nature and effects of endocarditis are described, leading up to heart failure in its many aspects; we are told how the adaptability of the circulation to effort can be examined clinically. The author devotes 100 pages to the treatment of heart failure, and describes in detail the employment of a great variety of drugs, exhibiting considerable optimism in translating pharmacology into therapeutics. Then a chapter is allocated to the mechanical effects of valve lesions on the heart itself, a chapter which the reader would be ill advised to regard as inspired. Only a short chapter is concerned with congenital heart disease, but it is a pleasure to note that co-arctation of the aorta is no longer enshrined amongst the extremely rare abnormalities. That there is a separate chapter on diseases of the heart muscle may perhaps be justified on systematic grounds, but it is none the less an anachronism; the theories of the nature of "hypertrophied" myocardium are fully stated. The relation of the heart to the body in general and to the ductless glands is sufficiently discussed. An interesting chapter follows on the effects of exercise, of high tension, and of diseases of the chest on the heart; but the reflex physiological regulation of blood pressure by the splanchnic vessels is not introduced into the description of pure high tension, and in consequence an important fallacy in this conception remains unexplored.

Cardiac irregularity—defects of rhythm—is thoroughly described in all its aspects, and this chapter may be recommended to English readers, since the views of the Viennese school on conduction in the auricle are thrown into a prominence, probably undeserved, but favouring a balanced appreciation of the position. A chapter on diseases of the pericardium is followed by a long description of the maladies of the blood vessels, including an

[2] *Die Krankheiten des Herzens und der Gefässe.* Von Dr. Ernst Edens. Berlin: J. Springer. 1929. (Sup. roy. 8vo, pp. viii + 1057; 239 figures. R.M.66.)

account of recent work on the reaction of the skin vessels to cutaneous injuries. An admirable chapter on angina pectoris is worthy of detailed study. It is noteworthy that Professor Edens does not sharply divide, for purposes of description, his cases into primary and secondary forms, as we are accustomed, rightly or wrongly, to do. The text finishes with a few pages on cardio-vascular neuroses, including the "effort syndrome."

HUMAN ANATOMY.

WE must confess to being at a loss to account for the fact that Professor JOHN B. DEAVER applied the epithet "Surgical" to his great book[3] on anatomy, for it has long seemed to us that it has no special claim to that adjective. *Gray's Anatomy*, for instance, contains at least as many, and as extensive, references to the bearing of anatomical facts on surgery as does Professor Deaver's in proportion to its size. This criticism does not imply, of course, that this work has not been or is not of great value to surgeons. A work of three quarto volumes, containing 2,168 pages superbly and profusely illustrated, cannot fail to be of great value for its illustrations alone, let alone the commentary on them in the text. The frequent references to steps to be taken in dissection, however, seem to confirm the impression that this is really a systematic work on descriptive anatomy.

Vol. i, of which the first edition was noticed in our columns in 1900 (*vol. i, p. 454*), deals with the scalp, cranium, brain, face, mouth, throat, and the organs of the special senses, with 124 plates, of which those representing the eye and its surroundings are specially numerous and instructive. Vol. ii, the first edition of which we noticed in 1901 (vol. i, p. 1083), *treats of the upper extremities* [*sic*], neck, shoulders, back, and lower extremities. Vol. iii is concerned with the joints of the lower extremities, chest, thorax, abdomen, and perineum. We are still of the opinion that in a work of this size more space and at least one plate *should have* been devoted to so surgically important a subject as the lymphatic vessels and glands of the pectoral region, even if two large plates, at present set apart to show the carrying angle of the elbow, were sacrificed to make room for it. The same remark applies to large plates the sole use of which is to show lines of skin incisions for *dissection* of the hand and some other parts. We have failed to find any plates illustrative of the *surgical* anatomy of inguinal or femoral hernia or any reference to congenital dislocation of the hip, the sacro-iliac joint, or troubles of the lumbo-sacral joint such as spondylolisthesis. The author states that the "spines of the vertebrae should lie in a straight line." Doubtless in a perfect spine they should do so, but he gives not so much as a hint that they very often do not, and that an irregularity of the line is not to be taken as a sign of injury or disease. The posterior superior spine of the ilium is mentioned, but we have failed to find any mention of the posterior inferior spine of the same bone. The line of incision for excision of the hip occupies one plate, but no notice is taken of the various incisions which have been recommended and used by various surgeons in order to obtain access to the hip-joint and for the performance of various procedures for dealing with arthritis and injuries of the joint and its neighbourhood.

We do not pretend to have given an account of more than a few features of this huge work. Were it a small portable volume we should expect omissions from want of space, but these three volumes weigh eighteen pounds, and it is grievous to think that much useful true surgical anatomy has been omitted to make room presumably for some rather elementary pathology and such descriptive anatomy as is to be found more readily in the standard works on human anatomy. What has the method of dissection of various parts to do with surgical anatomy, if that term has the same meaning in the United States as it has in Great Britain?

[3] *Surgical Anatomy of the Human Body.* By John B. Deaver, M.D., Sc.D., LL.D., F.A.C.S. In three volumes. London: W. Heinemann (Medical Books) Ltd. (8 × 11, vol. i, pp. xv + 551, 124 plates; vol. ii, vol. iii, pp. x + 763, 160 plates. Eight guineas the

THE ADRENALS.

DR. MAX A. GOLDZIEHER, formerly professor of pathology in the University of Budapest, and now director of the laboratories of the United Israel Zion Hospital, Brooklyn, New York, has rather opportunely written a comprehensive monograph on *The Adrenals: their Physiology, Pathology, and Diseases*,[4] which will be invaluable as a source of reference, and contains a bibliography occupying nearly one-fourth of the volume. Every subject connected with these glands is considered in such detail that the work is a mine of information. Following an account of their development and anatomy, the physiology of the suprarenal glands is exhaustively discussed in more than one-third of the volume, and their pathological anatomy in a section about half that length; the diseases of the gland are dealt with under the heading of patho-physiology, and in conclusion there is a chapter on organotherapy.

The discussions on high blood pressure and arterio-sclerosis are of special interest. High blood pressure is classified in two groups, renal and essential, the latter being attributed to a disorder of the vaso-regulatory mechanism which comprises the whole vegetative nervous system. It is argued that all the known etiological factors of genuine hypertension stimulate the adrenals, and that both the cortex and the medulla of the adrenals, together with the concomitant changes in other endocrine glands, are concerned in the production of raised blood pressure. The author very definitely states and illustrates his own observations and conclusions that in arterio-sclerosis and chronic renal disease the adrenal medulla is hyperplastic, and, further, that in renal disease and high blood pressure the muscular coats of the adrenal veins are greatly hypertrophied, and thus point to prolonged overactivity of the adrenals. A description is given of the varying size of the cortex of the adrenals in arterio-sclerosis—enlarged as a store of lipoids, or, when depleted and exhausted, small. In the full account of Addison's disease support is given to von Neusser's contention that it is due to impairment of the sympathetic system as a whole, and that whether the morbid process occurs in the end-organ—*that is*, the adrenals—or involves the impulse-conducting nerves or the spino-cerebral centres, the result is the same—namely, chronic insufficiency of the adrenals. The structure and clinical manifestations of primary tumours of the cortex and of the medulla are dealt with in full detail, and it is pointed out that bony metastases are rare in tumours of the cortex in contrast to what occurs in so-called renal hypernephromas or Grawitz tumours which are not of adrenal origin. Sexual precocity is said to be almost confined to females with cortical hypernephromas, three cases only in boys being admitted. In the account of tumours of the medulla the now familiar misprint of the Hutchinson (for Hutchison) type occurs. Reasons are given for regarding glaucoma as being due to endocrine disturbance.

In the concluding chapter on organotherapy the use of interrenin, the cortical hormone, fully discussed in the section on physiology, is advocated in cases of the genito-adrenal syndrome, menstrual disorders, infantilism, Graves' disease, and diabetes, but rather, it would seem, on hypothetical grounds than on the results of much clinical observation, for the author admits that experience is far too limited to form any idea of the contraindications of this form of treatment.

MEDICAL BACTERIOLOGY.

IN his preface to his manual of medical bacteriology Professor A. PHILIBERT expresses the view that in the study of bacteriology there is an increasing tendency to pay too much attention to the behaviour of bacteria on artificial media under laboratory conditions and too little to their manner of existence in the human body; according to this view the lesions and symptoms of disease are a better guide to the physiology of the microbe than its growth

[4] *The Adrenals: their Physiology, Pathology, and Diseases.* By Max Goldzieher, M.D. London: J. and A. Churchill. 1929. (Demy 8 pp. x + 436; 73 figures. 30s.)

[5] *Manuel de Bactériologie Médicale.* Par André Philibert. Paris: Masson et Cie. 1928. (5½ × 8, pp. xi + 551; 120 figures, 21 plates. 45 sans majoration.)

a culture. There is, however, nothing peculiarly revolutionary to be found in his teaching in the text, but the author does amply redeem his promise to write mainly from the point of view of the practising physician. Part 1 describes the methods to be adopted in examining all the different forms of pathological material—pus, buccopharyngeal exudates, cerebro-spinal fluid, blood, urine, etc. This is very well done; the directions are clear, and many seemingly small points, both in the collection of specimens and in subsequent manipulations which, if neglected, may lead the unwary to disaster, are wisely stated. In Part 2 the pathogenic organisms are described separately, particular attention being given to clinical bacteriology. Part 3 is devoted to general subjects such as immunity and anaphylaxis; this section is very briefly treated, and is the least satisfactory part of the book. The illustrations are nearly all coloured; they are very numerous and for the most part excellent.

PULMONARY TUBERCULOSIS.

THE attempts made during the last quarter of a century to control tuberculosis, even if the results have been disappointing, have at least produced a body of men trained in observation of the disease who, by intensive study, may ultimately find some solution of the problem. This specialization, however, seems to be leading to some disadvantages, to which Dr. R. C. WINGFIELD calls attention in the preface to his *Text-Book of Pulmonary Tuberculosis for Students*.[6] He points out that it is the general practitioner who supplies the State tuberculosis service with its material, but that the segregation of consumptives for observation and treatment in municipal dispensaries, special departments of hospitals, and special institutions has removed tuberculosis from the general departments of teaching hospitals just when it is important that every student should have the chance of studying the disease. Dr. Wingfield thinks that in the future the student may have to face a compulsory course in tuberculosis, but it is to be hoped that the position is not quite so serious as that. It is difficult to imagine it possible to teach examination of the chest in the out-patient room of a hospital without meeting with consumptive patients; the ubiquity of the disease guarantees such a supply, and even if the student has little time to master modern refinements in assessment and treatment, the general practitioner has little difficulty in applying general principles. The national scheme provides him with vast resources in trained specialists; while, if he prefers it, he may rely on the admirable textbook with which Dr. Wingfield has furnished him.

The book itself suggests to us another important question—namely, what is it that is really expected from tuberculosis schemes? We believe that in the minds of many people the object is the prevention of tuberculosis. The facts marshalled by Dr. Wingfield seem to indicate that such an object is hardly attainable on present lines. If it be true that tuberculosis is an acute infectious disease from which nearly 90 per cent. of the population suffers, mostly in infancy, and that, in general, phthisis is not the immediate product of an exogenous infection, but a recrudescence of infection from an existing tuberculous lesion in the lung or some other part of the body, it follows that the bulk of the work of those tuberculosis schemes which concern themselves with the adult population can have little effect in preventing pulmonary tuberculosis. The antituberculosis campaign can hardly claim to have produced any sudden change in the previous steady rate of decline of mortality from the disease; the value of the campaign appears to have been mainly evident in the relief of individual suffering. The benefits to the community, though real, are indirect, and not in themselves sufficient to result in the stamping out of phthisis.

Notwithstanding the network of tuberculosis officers and health visitors spread throughout the country, the detection, a large part of the treatment, and some measure of the prevention of the disease must continue to be the concern of the general practitioner. His most important function is early diagnosis; and for this he should be able to learn the principles as a student in hospitals with or without special tuberculosis departments. Thereafter his main function will be to fit the right treatment to the means and position of his patient. This is a matter upon which hospital training will not help much, but he has available two sources of information. The local tuberculosis scheme should be able to afford him help in the disposal of his patient. Unfortunately, while some of these schemes are working satisfactorily, others are still extremely inefficient. In the latter case the practitioner will be well advised to turn to such a book as that of Dr. Wingfield, from which he will obtain a sane estimate of what can, and what cannot, be done for a tuberculous patient; he will learn to appreciate the true function of the sanatorium, discriminating between patients suitable for treatment in hospital, in sanatorium, or in institutions for advanced cases; and he will discover that his main resource, apart from surgical intervention in special cases, is rest, coupled at suitable stages with graduated exercise. Dr. Wingfield quotes usefully a statement of Powell and Hartley that "good results are obtained in patients who have never been higher than the galleries of the Brompton Hospital." Equally good results have been achieved in patients who have been consigned to homes for the dying in London! But, however good these temporary results may be, Dr. Wingfield points out that when a physician undertakes a case of phthisis he undertakes the supervision of the case for the patient's whole life—or for as long as the patient continues to employ him. Arresting statements such as this should make Dr. Wingfield's book valuable not only to medical practitioners, but also to many other people who long for the prevention of tuberculosis, especially if they remember that nearly 40,000 people die annually from the disease.

[6] *A Text-Book of Pulmonary Tuberculosis for Students.* By R. C. Wingfield, M.B.Oxon., F.R.C.P. London. Constable and Co., Ltd. 1929. 5½ × 9, pp. xvi + 401; 92 figures, 52 plates. 31s. 6d. net.)

THE METABOLISM IN PHTHISIS.

IN his admirable volume on the disturbances of the nutritive exchanges in pulmonary tuberculosis,[7] Dr. MONCEAUX gives an elaborate résumé of the literature of the subject, mainly physiological and chemical in its general nature, backed by over five hundred references to original papers dealing with its many aspects. Beginning with the metabolism of the proteins and their products of decomposition, he brings forward good evidence to prove that in phthisis there is a defect in the processes of oxidation: the patient with advanced disease produces less urea and a larger figure for the total nitrogen excretion than the normal, an excess of urinary amino-acids in the urine, and an excess of oxalic acid in the blood, and the same is true even in the earlier stages of the disease, though naturally in a lesser degree. Discussing next the metabolism of the fats, he shows that the utilization of the fats in the food is inadequate, and that the liver, found to show fatty infiltration or degeneration in about 70 per cent. of the cases, fails to deal in a normal manner with the fats reaching it from the intestine. Here, again, Dr. Monceaux finds a flagrant insufficiency of oxidation; and he argues that in patients with well-developed phthisis there is also a deficiency in the amount of cholesterin in the blood, though in early cases this amount is above the normal. He finds little evidence to show that there is any loss in the power of oxidizing carbohydrates, speaking generally, but gives reasons for recommending the use of malted foods in phthisis. He discusses the gaseous exchanges and the acid-base equilibrium of the body at some length, and in the sixth section of his book drives another nail into the coffin of the "decalcification" theory in pulmonary tuberculosis that was so widely supported twenty years ago, while pointing out that at least 2 grams (31 grains) of calcium oxide a day are required in the diet of a phthisical subject. Discussing the pigment carotin, Dr. Monceaux points out that there are reasons for believing that it is oxidized less readily than in health, and so tends to accumulate in the tissues of patients with pulmonary tuberculosis, giving rise to the straw-yellow tint so often seen in their skins. The last two sections of the volume deal with the general conclusions to be drawn from

[7] *Troubles des Echanges Nutritifs dans la Tuberculose Pulmonaire.* Par R. Monceaux. Saint-Cloud: Girault. 1929. (Roy. 8vo, pp. 445; 12 figures, 8 of which are coloured. 75 fr.)

the preceding sections, and the light they throw on the therapeutics of phthisis. It is argued that metabolism in general is slowed down, and that the processes of oxidation are diminished rather than exaggerated; the activities of the liver, the thyroid gland, and the suprarenals are much impaired in anabolism as well as in catabolism.

It is impossible to summarize the therapeutic suggestions to which Dr. Monceaux has been led by his elaborate study of the metabolism in phthisis, and the thirty pages in which he sets them out should be read by all medical men who are interested in this most important subject. The author evidently believes that it is in dieting rather than in drugs that progress in the treatment of pulmonary tuberculosis is to be made. The book is well and temperately written, and contains a mass of interesting information.

NOTES ON BOOKS.

A BOOK which has reached a seventh edition hardly needs a review, at least in the way of recommendation. It is obvious that it has acquired a reputation and a public of its own, whose advocacy is more effectual than any review. The seventh edition of *Birch's Management and Medical Treatment of Children in India*[8] is also the thirteenth edition of H. H. Goodeve's *Hints for the General Management of Children in India*. This little work was published on March 15th, 1844, and thus, if we consider the present to be the same book as Goodeve's, it is probably the oldest medical work still in constant use. It is true that there is not much in common between Goodeve's original little book of about a hundred pages, which would go in a small pocket, and the present large octavo of nearly 500 pages; but the last is a direct descendant of the first. The seventh edition of Goodeve's tiny booklet, published in 1879, was entirely rewritten by the late Surgeon Major E. A. Birch, and for several editions was known as Birch's *Children in India*, little of Goodeve's original work being left. Goodeve's name was dropped out of the title long ago, and now Birch's name remains only as one word on the title-page. The book has been carefully and thoroughly brought up to date by the present editors. Chapters have been contributed on diseases of the ear, nose, and throat by Dr. N. J. Judah, and on snake-bite by Lieut.-Colonel R. Knowles, I.M.S. The general get-up, paper, type, and illustrations are good, and we have noticed only three misprints.

The Constitution of Sugars[9] is the title of a little work by W. N. HAWORTH discussing the results of newer researches on the sugars. Dr. Haworth has been himself a notable contributor to research in this domain, and has studied closely the possible inferences to be deduced from the work done. He is thus well qualified to present a discussion of the available evidence for and against alternative views of constitution. His exposition of the subject will be welcomed by the various group of sugar chemists as a most useful summary of the accepted facts combined with a stocktaking of the debatable questions.

Dr. CHARLES RICHET, jun., in his *Précis de Pathologie Expérimentale*,[10] gives in a minimum space an extensive survey of recent research in pathology from a point of view that is not usual in English books. It should be of interest to candidates for the M.D. or M.R.C.P. The illustrations are simple and instructive. The triple index (authors, subjects, and chapters) is useful in a reference book of this kind. The few misprints are too evident to be misleading, but (as in so many Continental publications) the binding is far from substantial.

A monograph on *The Development of the Psycho-Analytical Theory of the Psychoses*,[11] by Dr. JOHN RICKMAN, has been published as a supplement to the *International Journal of Psycho-Analysis*. The book is a reprint of a series of papers which have appeared in the *British Journal of Medical Psychology*. In a short preface Dr. Ernest Jones observes that the psycho-analytical contributions to psychiatry are so scattered in the general literature that the onerous task of collating and presenting the results in an intelligible form is one which earns our gratitude. The reader will endorse this statement. Dr. Rickman's [illegible] references to no fewer than 500 papers [illegible] of the material is admirable, and the highly complex subject-matter is lucidly presented. Appended to this work is a table of psychical mechanisms showing their relation to the various forms of mental disorder. This authoritative compilation will be found useful to the psychiatrist as well as to the psycho-analyst.

The official first-aid handbook[12] of the St. John Ambulance Association was originally written by the late Sir James Cantlie in 1901 and subsequently revised by him in 1908, and by a committee in 1917. The manual has now been brought up to date by another committee, and before beginning the revision criticisms and suggestions were invited from lecturers, examiners, and "first-aiders" in all parts of the world. The thirty-eighth edition thus produced is an up-to-date volume, still retaining its conveniently small bulk, and still of the same general character as its forerunners, but otherwise an authoritative modern textbook of all that is best and most useful for first aid to the injured.

The first series of *Instructions for Patients*, drawn up by Dr. T. T. B. WATSON, was noticed in our issue of November 3rd, 1928 (p. 799). Further leaflets (Nos. 10, 12, 13, 14) have now been issued by the publishers, Messrs. H. K. Lewis and Co., Ltd., 28, Gower Place, W.C.1. (25 for 1s.; holders to fit, 9d. each.)

[8] *Birch's Management and Medical Treatment of Children in India.* Seventh edition, by V. B. Green-Armytage, M.D., F.R.C.P., Lieutenant-Colonel I.M.S., and E. H. Vere Hodge, M.D., M.R.C.P., Major I.M.S. Calcutta and Simla: Thacker, Spink and Co. 1929. (Demy 8vo, pp. x + 482; [illegible] 10.)

[9] *The Constitution of Sugars.* By Walter Norman Haworth, D.Sc.Ma[illegible] F.R.S. London: E. Arnold and Co. 1929. (Med. 8vo, [illegible] figures, 2 plates. 8s. 6d. net.)

[10] *Précis de Pathologie Expérimentale.* Par le Dr. Charles Richet fils. Bibliothèque du Doctorat en Médecine. Paris: J. B. Baillière et Fils. 1929. (5 × 7½, pp. xi + 331; 89 figures. 40 fr.)

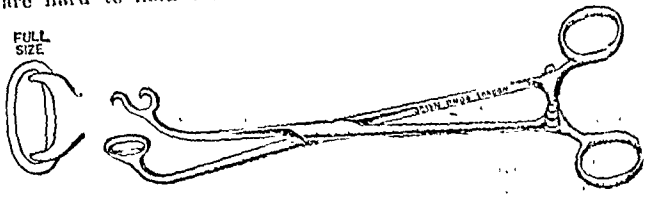
[12] *First Aid to the Injured.* Originally compiled by the late Colonel Sir James Cantlie, K.B.E., M.B., F.R.C.S., V.D., and revised by committees. Thirty-eighth edition. London: The St. John Ambulance Association. 1929. (Demy 16mo, pp. 250; 105 figures.)

PREPARATIONS AND APPLIANCES.

A TONSIL-HOLDING FORCEPS.

MR. HAROLD E. RAWLENCE, F.R.C.S., writes: Many more enucleations of tonsils are now being performed, and, with experience, the surgeons find two varieties of tonsil which are hard to hold while enucleation is taking place. The first

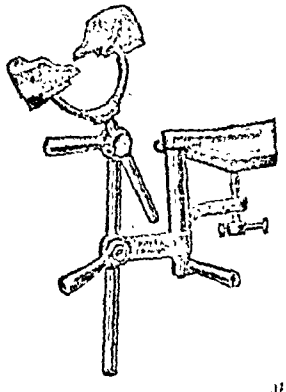


is the big, very soft, spongy, and friable tonsil; the second is the retracted and buried tonsil, which is often very septic and adherent.

The forceps now made by Messrs. Down Bros. for me, and here illustrated, will, I hope, overcome both these difficulties. The length, the curve, and the area of the grip have all been carefully calculated in order to obtain a quick, firm hold.

HEADREST FOR BRONCHOSCOPY.

Dr. LESLIE POWELL (aural surgeon, Royal Berks Hospital, Reading) writes: The headrest for bronchoscopy and oesophagoscopy shown in the accompanying illustration has been made for me by Messrs. Mayer and Phelps. It consists of a dental headpiece placed so that the (normally) lateral pieces are anterior and posterior and the edge of the anterior piece fits into the occipito-atlantal angle. This is attached through rods and two universal joints to a plate and screw, by which it can be fixed to any flat table. With two pillows under the shoulders the desired position can easily be attained. I have used this apparatus for many cases, and find it most efficient, and no holding by an assistant is required. It is particularly useful for those who, like myself often have to work without skilled assistance.



ANTISEPTIC JUJUBES.

"Eumenthol" jujubes are pastilles prepared by Hudson Eumenthol Chemical Company of Sydney, N.S.W. They contain a variety of antiseptic volatile oils, the chief of which is oil of eucalyptus. The manufacturers quote analysts' reports showing that the jujubes have a carbolic acid coefficient of 4.1, and also describe experiments which prove that the essence exercises bacteriostatic action at a concentration of 1 part in 1,280 parts of bouillon.

PROVISION FOR THE CARE OF EPILEPTICS.

AN INTERNATIONAL SURVEY.

It is the duty of a local education authority in Great Britain to ascertain the number of epileptic children in its area, and to make suitable provision for the education of those among the number who are unable for any reason to profit by the education given in the ordinary elementary school. Such children may, however, be sent to a residential school or institution only with the consent of their parents, such consent not being unreasonably withheld. It is the duty of the guardians of the poor to deal suitably with those epileptics, whether children or adults, who need communal care by reason of their destitution. In addition, there are several voluntary agencies which concern themselves in helping sufferers from epilepsy; and, inasmuch as this condition is often associated with feeble-mindedness, all the provisions which the law has made for dealing with the latter condition are available for feeble-minded epileptics. Under these various auspices a good deal of provision has been made, but accommodation in homes, colonies, or schools can scarcely be described as adequate, and its suitability for its purpose varies very considerably. In the Annual Report of the Chief Medical Officer of the Board of Education for 1927 the following paragraph appears:

"The number of children ascertained by local education authorities to be unfit by reason of severe epilepsy to attend the public elementary schools in 1927 was 2,652. For the accommodation of cases of severe epilepsy there are six residential special schools, providing between them for 525 epileptic children. It is manifest accordingly that there are many epileptic children for whom residential accommodation is required, but for whom it is not forthcoming. Many of these children are capable of profiting from the education provided in a residential school, and apart from this there are many for whom it is quite impossible for the parents to give the required attention in the home without sacrificing the interests of other children in the family. It is much to be desired, so soon as financial circumstances allow, that the local education authorities should take steps to secure the suitable medical and educational treatment of the children of this group."

It is probably true that the segregation of epileptic children of approximately average intelligence is, except in the most severe cases, undesirable. Dr. Auden, the school medical officer for Birmingham, has pointed out that with such children "there is very generally a peculiarly self-centred mental outlook which is readily intensified by exclusion from the ordinary pursuits of their fellows." If, however, these children are, wherever possible, retained in the ordinary elementary school they require some special attention and supervision, and should be placed on a special register and re-examined medically from time to time.

If a census of epileptics throughout the country could be secured it would almost certainly reveal that the magnitude of the problem is considerably greater than is commonly recognized. Such a census within the area of the county of Surrey has, in fact, been made by the Permanent Committee on Epileptics, and the results are disquieting. This committee, under the auspices of the Charity Organization Society, consists of representatives of a number of homes, colonies, hospitals, and associations interested in the subject, and it has now performed a further useful service by making an inquiry through correspondents in various parts of the world as to the provision that is made for the care and treatment of epileptics. The best previous information with regard to this was to be found in the evidence submitted to the Royal Commission on the Feeble-minded, whose report was published in 1908. A summary of the results of the recent inquiries by the Permanent Committee is therefore of much interest and importance.

Provision in the United States and Holland.

It was in Holland and in certain of the United States of America that practical steps for the special care of epileptics were first taken. As long ago as 1879 an attempt in this direction was made in Ohio, but it was not till 1893 that a State hospital was actually opened for patients in Gallipolis. Other colonies or hospitals speedily followed in New York State, in Massachusetts, and in New Jersey, and later still institutions of a similar nature were founded in a number of other States. In very many of the States, however, no special provision of any kind is yet made for epileptics, and State legislation makes no reference to their needs or to the problems raised by the existence of the condition. As the report of the committee says: "The tendency in the United States appears to be to combine the care of epileptics with that of the mentally defective In some States admission to the special institution fo epileptics can be gained only on committal, as in the cas of the feeble-minded. The marriage of epileptics is fo bidden by the laws of certain States, and in at least o instance epileptics are included in the provisions of t sterilization law." The general condition as to incide and care is thus set out:

In the United States of America the institutional care of feeble-minded and epileptic is very largely a public matter. ... the census of feeble-minded and epileptics in institutions under taken by the Federal Census Bureau in 1923, it was found that of the 51,751 resident patients for whom schedules were received, only 7.5 per cent. were in private institutions; 90 per cent. were in State institutions, and 2.6 per cent. in other public institutions.

This was the first special census of epileptics taken by the Census Bureau, and showed 8,777 epileptics in institutions for epileptics, 4,159 in institutions for the feeble-minded, 10,016 in institutions for the insane, and 1,066 in almshouses (workhouses), making a total of 24,018 epileptics under institutional care. It is stated in the census report that no adequate data exist relative to the number of epileptics in the population at large, but that it is believed, however, that the number greatly exceeds the number in institutions. It is added that available data also give no clue as to the probable increase or decrease of epilepsy.

It is of interest to note that of the 8,777 patients in institutions for epileptics, 98 per cent. were whites, and only 2 per cent. were negroes. It is stated that this very low ratio of negroes is probably due to the fact that in many States negroes are not admitted to the institutions as readily as are whites.

The total number of institutions covered by the census was 139. Of this number, 122 were institutions for the feeble-minded and 17 were institutions for epileptics. In addition, 3 State and 12 Federal hospitals for mental disease returned schedules for epileptics.

For centuries the people of the Netherlands have been conspicuous for the provision they have made, usually of a voluntary charitable nature, and often in connexion with Protestant or Roman Catholic Church organizations, for the needy or afflicted, especially among children and old people. It is in accordance with their tradition that perhaps the earliest society for the actual care of epileptics was founded in Holland. As the committee's report tells us:

There are two societies in the Netherlands concerned with the care and treatment of epileptics:

1. The Christian Society for the Nursing of the Epileptic at Haarlem. This society was founded in 1882 at a time when epilepsy had but rarely been studied. It devoted itself at first to the care of the chronic cases, but latterly it has concerned itself more and more with the study of epilepsy and its treatment. Its establishments (at Haarlem for women and at Heemstede for men) are now centres of research as well as treatment. These institutions are organized on the lines of colonies, and the inmates are, where possible, doing profitable work. The homes act also as training schools for nurses. The society is managed on a Protestant-Christian basis. It receives no subsidy from State or municipal funds, but is maintained by voluntary contributions and by the payments of patients. The municipalities contribute towards the maintenance of indigent patients. The admissions and discharges during 1927 were as follows:

	Men.	Women.	Total.
Resident on January 1st, 1927	192	218	410
Admitted during 1927	51	25	56
Discharged during 1927	36	220	407
Remaining at December 31st, 1927	187		

2. The Netherlands Society for Epilepsy, founded at The Hague in 1902, has as its object the scientific examination of the origins of the different forms of epilepsy and methods of prevention and cure. Its methods differ from those of the older society. It maintains a hospital at Amsterdam (built in 1922), with up-to-date equipment and with a capacity of 40 beds. There is no intention of retaining patients for the rest of their lives. They are kept at the hospital for a few months only, treatment being continued afterwards at local clinics, which have been established at Amsterdam (in connexion with the hospital), Rotterdam, The Hague, Utrecht, and Zwolle. The society has corresponding

physicians at Arnhem, Heerlen, 's-Hertogenbosch, Hilversum, and Maastricht. The Amsterdam Hospital has an after-care department and a school for nurses. The society receives a Government subsidy up to a maximum amount of fl. 15,000 per annum, which about covers the deficit between expenditure and other income. Its other income is derived from patients' payments and voluntary contributions. The maintenance of patients is sometimes paid for by the municipal authorities. Admissions and discharges at the Amsterdam Hospital during 1927 were as follows:

	Men.	Women.	Children.	Total.
Resident at January 1st, 1927	8	11	11	30
Admitted during 1927	30	31	37	98
Discharged during 1927	34	34	32	100
Remaining at December 31st, 1927 ...	4	8	16	28

At the Rotterdam Clinic 1,388 patients were treated during the year 1927, their total attendances amounting to 7,288.

No legislation has been enacted in Holland with special reference to epileptics. Epileptic children are taught, if necessary, at schools for backward children. Epileptics are to be found in all mental hospitals in Holland and at the institution for imbeciles at Leur.

France and Germany.

In France and in Germany the position is as follows:

In France, by the provisions of a law passed in July, 1905, epileptics are placed in the same category with invalids and incurables, and are entitled, where necessary, to assistance from public funds, either by being placed in a hospital or asylum or by being given a monthly allowance; the allowance is fixed at a maximum of 70 francs for Paris, and is given to those of 16 years and upwards. There is no other special reference to epileptics in the French law.

If an epileptic is sane, or suffers from mental deficiency, he may be admitted to a regional institution or private asylum subsidized by the State. There are two regional hospitals in Paris where epileptics are received: La Salpêtrière and Bicêtre. There are 39 institutions in the provinces. Of these, 35 admit feeble-minded and imbeciles, and have a special section for epileptics. The following four institutions admit epileptics exclusively: L'hospice d'épileptiques de Haut Barieux (Allier); l'hospice d'épileptiques de la Devoze (Cantal); l'asile privé de la Teppe, Tain (Drome); les asiles John Bost, La Force (Dordogne).

Until 1923 no provision was made for the treatment of epileptics living at home with their families. In that year, however, Dr Toulouse, senior physician of La Clinique de l'Asile Ste Anne, and director of the mental and neurological prophylactic service, instituted neuro-psychological consultations. New neuro-psychiatric clinics are shortly to be opened in Paris, Lyons, and Bordeaux.

The public assistance authorities of Germany possess wide powers for the care of the sick, including epileptics. They are required, where necessary, to provide institutional care. The following public institutions receive epileptics only: Berlin-Wuhlgarten Municipal Home for Epileptics; Kork (Baden) Home for the Treatment and Care of Epileptics; Johannisthal bei Suchteln (Rhine Province); Breslau Municipal Home for Epileptics (Herrenprotsch).

At the first-named institution there are now 1,298 adults and 172 children. There is a resident staff of nine medical officers. Occupation for patients is provided in domestic work, gardening and agricultural work, carpentry, bookbinding, tailoring, brush-making, and strawplaiting. Most of the patients are paid for by the municipal authorities; a few are maintained by the national health insurance authorities up to a maximum period of twenty-six weeks, after which the municipal authorities usually become responsible. Patients of all mental grades are admitted, including the insane.

There are other institutions, partly supported by the local authorities and partly by private charity. A number of homes are maintained by the German Caritas-verband and by the Central Committee for Home Missions of the Evangelical Church. At Bielefeld in Westphalia is situated the famous colony, founded by Pastor von Bodelschwingh in 1867, which has served as a model for the modern epileptic colonies in both England and America.

For epileptic children there are some special institutions, which are usually attached to homes for adults. The Berlin-Wuhlgarten home is stated to have a specially good department for children.

In Belgium no legislation has been enacted with special reference to epileptics, but epileptic men are cared for by the Brothers of Charity and epileptic women by the Sisters of Charity, who maintain several institutions, one of them for children. Only those of normal mentality are received, and dangerous cases are transferred to a separate institute.

In Switzerland there are five institutions for epileptics, receiving both children and adults. All are maintained by voluntary contributions, except that one (in Zürich) receives some subsidy from various cantonal authorities. There is no Swiss federal law concerned with epileptics apart from those who are also mental defectives, but the Swiss c[illegible] on parents the obligation to provide education for their children according to their means and to the mental and physical condition of the child.

It will be seen, therefore, that on the Continent of Europe the most interesting development is taking place in Holland; that Belgium, France, and Switzerland rely largely on voluntary enterprise to deal with the same epileptic; that in Germany, while some institutional provision is made by the authorities, much is still done by voluntary agencies; and that in the newer countries of post-war Europe little has as yet been done for the epileptic.

This report of the Permanent Committee on Epileptics, while admittedly and almost necessarily incomplete, certainly justifies their hope that "what has been obtained will be not only of interest but of service as some indication of what is being done abroad to-day to deal with the epileptic."

SMALL-POX.

STATEMENT BY MINISTRY OF HEALTH.

As there appears still to be some misunderstanding in this country and America regarding the prevalence of small-pox in England, the Ministry of Health has considered it advisable to issue the following statement on the subject dated May 23rd.

Small-pox of mild degree has been more than usually prevalent in England and Wales since 1922. The actual figures and deaths have been as follows:

Year.	No. of Cases.	No. of Deaths.	Mortality (per cent.).
1922	973	27	2.77
1923	2,504	7	0.28
1924	3,797	8	0.21
1925	5,354	6	0.11
1926	10,141	11	0.11
1927	14,787	36	0.24
1928	12,420	53	0.43
*1929	3,283	8	0.25

* First quarter (provisional figures).

The distribution of these cases has been chiefly in certain industrial areas in South Wales, Durham, Derbyshire, and the West Riding of Yorkshire, where vaccination among adolescents and adults has been relatively neglected. The increased movement of the people, together with the extreme mildness of degree of infection, has, of course, also tended to disseminate this malady.

The small-pox cases which arose from infection from the *Tuscania*, which reached England from Bombay at the end of March, numbered 51 (out of 1,554 passengers and crew), 35 of which cases occurred in England and 16 in Scotland. Ten cases proved fatal. These cases, unlike those referred to above, were of severe degree, and were imported. There have been no further infections from the *Tuscania* since April. Public opinion may therefore be reassured that the *Tuscania* outbreak, which was in any case narrowly restricted, has definitely terminated.

Small-pox of mild degree has been prevalent in Europe and America during the last few years, but now shows signs of abatement; and in England we are in this respect no worse off than we have been for a quinquennium.

The general health of Great Britain is exceptionally good and compares favourably with that of other great nations and its own past records. Indeed, the total death rate of 11.7 per 1,000 is within 0.1 per cent. the lowest on record. The infantile mortality, always a living and susceptible index of national health, is 65 per 1,000 births, the lowest ever recorded. The total number of deaths from all forms of infectious disease in 1928 was 83,660 (including all forms of tuberculosis, pneumonia, etc.), as compared with 96,571 in 1927. With a declining general mortality, a declining infant mortality, and a falling zymotic death rate, it may be said that the health of England is satisfactory.

Previous statements issued by the Ministry of Health have appeared in the *British Medical Journal* of April 20th (p. 742) and May 4th (p. 816); and a report on small-pox cases from the *Tuscania*, by Dr. A. S. M. Margetson, medical officer of health for Glasgow, was printed in the issue of May 11th (p. 874).

THE WORKING OF A PRIVATE PATIENTS' WARD.

A YEAR'S EXPERIENCE AT THE NORFOLK AND NORWICH HOSPITAL.

WE are indebted to Dr. A. J. Cleveland, O.B.E., F.R.C.P., honorary physician to the Norfolk and Norwich Hospital and medical officer in charge of the electrotherapeutic department, for the following instructive account of the organization and management of a ward for private patients.

A private ward was opened at the Norfolk and Norwich Hospital on April 20th, 1928, for patients whose incomes came within the following limits:

1. Single persons with an annual income under £350.
2. Married couples without children under the age of 16 and an income of £450 per annum.
3. Widows and widowers with a child or children under 16 and an income of £450 per annum.
4. Married couples with a child or children under 16 and an income of £550 per annum.

The object of the ward is to provide "hospital treatment" for those who cannot afford to pay the ordinary private nursing home fees, but whose financial position places them above the class for which the general wards are intended.

In connexion with this private ward an insurance scheme was instituted. An annual payment of 30s. entitles the subscriber, his wife, and children to full in-patient "hospital treatment," and to certain out-patient treatment, provided his income comes within the above limits. Before admission a consultation between the subscriber's doctor and a member of the hospital staff must take place, the fee for which is not included in the subscription. No patient shall remain in for more than four consecutive weeks without the sanction of the managing committee; maternity, mental, and infectious cases are not admitted. There are no "extras." The patient can be examined or treated in any of the special departments of the hospital without further payment.

Patients who have not joined the insurance scheme, but whose incomes fall within the same limits, can be admitted to the ward on payment of £4 per week, *plus* a fee for the physician or surgeon in charge, which shall be inclusive, but which shall not exceed fifteen guineas. All patients in the private ward must be under the care of a member of the medical staff of the hospital. The provision in this private ward of hospital treatment for patients of the financial position specified has enabled the hospital board of management to refuse treatment in the general wards to anyone with an income of over £300 per annum. Anyone whose income exceeds that amount should either go into the private ward or, if his income comes above the standard laid down for that, into a private nursing home.

The private ward is apart from the main hospital buildings, and consists of separate single rooms. The original number was twelve, but, on January 5th, 1929, two additional ones were added. As the ward has been open for a year it is possible to give an account of its working.

The number of patients admitted during the twelve months was 249; of these, 44 were members of the insurance scheme and 205 came in under the £4 per week scheme. The number joining the insurance scheme is a little disappointing; 760 have joined up to date. The reason why this figure is not greater ; that there has been difficulty in getting the scheme known; ut the steady rate of increase in subscribers gives ground for belief that this is the only reason, and the satisfaction which the patients express with the accommodation and treatment provided is an effective, if somewhat slow-acting, method of advertising.

Taking the insurance part of the scheme first; no patient can receive treatment until six months after the payment of his first premium. The amount subscribed is distributed as follows:

A first charge of £4 per week per in-patient is paid to the hospital. A second charge of an equal amount, but not exceeding a total of fifteen guineas per patient, is paid to the medical officer in charge. At the end of the year the baiance in the insurance fund is divided into three equal parts: (1) one to the hospital; (2) one to a reserve fund; and (3) the other to the honorary medical staff. Estimating the sickness incidence as 4 per cent. per annum, and allowing for each patient to be in for three weeks, there would be for the year a surplus of £405 after payment of the first and second charges (with a total of 750 subscribers). It is not possible to give an accurate figure for the sickness rate during the first year, as the number of subscribers has been steadily increasing all the year, but it has certainly not exceeded 4 per cent. at three weeks per patient, which is equivalent to twelve weeks' occupation of a bed for every 100 contributors. There is therefore every reason to believe that this part of the scheme is financially sound.

With regard to those coming in on the £4 per week basis the financial success of the scheme depends on whether the payment of that amount is sufficient to meet the cost of treatment and maintenance provided by the hospital. The average cost per in-patient for 1928 for the whole hospital, including those in the private ward, was £2 16s. 1d. A careful estimate of the extra cost of a patient in the private ward over that of one in the general ward brings the total for the former up to £3 19s. 1d. per week. The chief items in which an increase occurs are nursing, food, heating and lighting, and furniture. It has been decided to raise the charge to four guineas per week. This slight increase will scarcely be noticed by the patients, and the extra charge will leave a small surplus, which can be put to the capital account.

In starting this private ward the chief financial difficulty was the capital outlay. Fortunately a building was available. The amalgamation of the Norfolk and Norwich Eye Infirmary with the Norfolk and Norwich Hospital and the provision of an "eye ward" in the hospital proper left the premises of the Eye Infirmary vacant. The cost of making this building suitable for the private ward came to £1,600, and to meet this outlay by the hospital the honorary medical staff guaranteed half this sum out of the fees they would receive; eight members of the Board of Management very generously guaranteed the rest. It will not be necessary to call up this latter part of the guarantee, as by giving 25 per cent. of their fees towards paying off the capital expenditure the medical staff will have paid off the whole amount in three years; if the surplus from the contributory members' payments remaining after their maintenance and treatment costs have been paid is placed to the capital account the debt will be cleared in two years. That the scheme has been a success is shown by the fact that there has rarely been a bed empty, and the waiting list has varied from 2 to 17.

Many acute cases have had to be accommodated at first in the general ward, so that for the hospital to derive full benefit from the private ward it will have to be enlarged, and the provision of a further six beds is contemplated. From the patients' point of view the insurance scheme is a very cheap one; in fact, considering what is provided, it has been suggested that the premium of 30s. per year is too small. But the object of the scheme was not to make money; it was, as has been stated, the provision of hospital treatment for those who could not afford full nursing home fees, but who were able to pay for their maintenance and a small sum for their treatment. All fees are paid by the patients to the house governor of the hospital, and he does all the secretarial work connected with the scheme, for which the honorary medical staff pay him an honorarium based on a percentage of their fees. It is estimated that two-thirds of the patients admitted would otherwise have gone into the general wards, and the remaining third could only have afforded the lowest fees charged for treatment in a private nursing home.

The management of the private ward is in the hands of a committee of eleven, appointed by the Board of Management of the hospital, on which are two members of the honorary medical staff.

It is the custom in Norwich and Norfolk, as elsewhere, for all accident cases to be taken at once to the hospital, whatever the financial means of the patient may be. If the case is serious it is admitted straight to the general ward, and many patients have been treated for nothing who could quite well have paid and would willingly have done so, but that their condition precluded the possibility of their being moved to a nursing home. If the private ward is enlarged sufficiently to allow of one or two beds being kept free for emergencies, these patients will have the advantage of a private room, and the hospital and the medical staff will be paid adequately for their services.

British Medical Journal.

SATURDAY, JUNE 1ST, 1929.

THE MOTT MEMORIAL VOLUME.

SIR FREDERICK MOTT died during his year of office as president of the Royal Medico-Psychological Association, and at a meeting of members shortly after his death it was felt that some appropriate way of expressing gratitude for all that he had done for them and for psychiatry must be found. A mere memorial in bronze or stone appeared to the members to be insufficient, and Dr. Frederick Golla, who was present, spoke of the custom abroad whereby all who so desired could contribute to a publication some fragment of appreciation or some useful piece of work inspired by the master they wished to commemorate. Dr. J. R. Lord, who succeeded Sir Frederick Mott as the president of the association, was captivated by this suggestion, and took the necessary steps to carry it out. A committee came into existence to see the matter through, and the result is the Mott memorial—a volume, edited by Dr. J. R. Lord, entitled *Contributions to Psychiatry, Neurology, and Sociology*,[1] and dedicated to Sir Frederick Mott by his colleagues, friends, and former pupils.

Those who are interested in the problems of psychiatry, neurology, and the physiology of the nervous system will naturally feel impelled to make themselves acquainted with the contents of this memorial volume. The editor and the committee are to be congratulated on the result of their efforts. The subject-matter covers a wide range, and many distinguished observers have been glad to make their contribution in honour of the memory of a great teacher, investigator, and physician. The diversity of topics discussed in this volume serves to remind its readers of the breadth of Mott's activities and of the extent to which he was responsible for definite additions to knowledge. The majority of contributors refer directly to his work, and many of the papers have been stimulated by his researches or are elaborations of his views. In a striking tribute to Mott, whom he happily terms "this splendid man," Professor C. von Monakow gives an estimate of his friend's life and career—a summary which affords us glimpses into the greatness of his achievements. Monakow points out that Mott, with all his extensive scientific work, maintained his very high position as a physician, and not only took a great and undiminished interest in his practical professional activities, but devoted much time to them. Furthermore, as regards psychiatry, he applied himself with much zeal and enthusiasm to the study of problems that extend into the fields of general biology and psychology, problems that have scientific, medical, and social significance. Thus he was particularly interested in the question of the early treatment of mental disorders. This is recognized by Sir Hubert Bond, who, very appropriately, begins his impressive contribution on the prevention and early treatment of mental disorder with the following quotation from an article by Mott: "Every effort should therefore be made to induce the patient, the friends, and the practitioner to seek skilled advice or treatment with as little delay as possible. This can only occur if the fear of certification and of being sent to an asylum be removed, and by the provision of greatly increased facilities for early treatment in clinics attached to the general hospitals or suitable hospitals affiliated with the general hospitals." We all know how strenuously the writer of these words worked to bring about the necessary facilities for treating the early case. To his unremitting efforts, enthusiasm, and capacity for overcoming obstacles the success of the Maudsley Hospital—the first psychiatric clinic on a large scale in this country—is in a large measure due. No one who has been associated with this hospital will be in any doubt as to the value of his services in its early days. In other directions also he had helped this movement, and, in her contribution to this volume, Dr. Helen Boyle observes that Sir Frederick Mott's illustrious name is at once brought to mind when one thinks of the early treatment of mental and nervous disease. She refers in this connexion with gratitude to his encouragement and support of the Lady Chichester Hospital in the struggles of its youth, by sending patients to it, by supporting it in public, and by many kindly words in private.

To think of Mott only as a neurophysiologist and pathologist would be to lose sight of the extent of his activities. He was a great force in psychiatry, and influenced its development in all directions. He was always deeply concerned in the welfare of the patient, and insisted on the necessity of active treatment with a view to bringing about recovery. He was equally the friend of the chronic asylum patient: he deplored stagnation, monotony, and inactivity, advocating individualized study and carefully and scientifically planned occupation therapy. Thus he will be remembered not only as a scientist, but also as a physician with a deep interest in the welfare of the sick in mind or body. By his large circle of friends in this country and abroad—for his reputation stood high in foreign countries as well as at home—he will always be affectionately remembered on account of his personality. He was essentially human and kindly, uncomplicated, understandable, simple and direct in the expression of his views, and without trace of affectation.

Frederick Mott was a man who will certainly be remembered by those who knew him quite as much for his personal qualities as for his scientific achievements. For this reason the memorial volume will be very much valued. It will not only enrich the mind but, in the case of many of its readers, it will stimulate pleasant memories of an old and valued friend. To such readers the many personal references in the volume will be particularly welcome. Professor W. D. Halliburton gives some delightful recollections of his long and intimate friendship with Mott, which lasted well over half a century. The volume opens with this personal appreciation, and appropriately concludes with the one by Professor C. von Monakow to which we have already referred. This eminent Swiss neurologist finishes his article with an impressive tribute, which will give much pleasure to his English colleagues: "Sir Frederick Mott," he writes, "was not only a distinguished neurologist and physician. He was refined, noble, and modest, and a kind and loyal colleague. Wherever he worked, and with whomsoever he came in contact, he won admirers and friends. To those whom he honoured with his most intimate friendship he remained faithful and constant to the end of his life."

Edited by J. R. Lord, C.B.E., M.D., F.R.C.P.E., on behalf of the Mott Memorial Committee. H. K. Lewis and Co., Ltd. 1929. (Sup. roy. 8vo, pp. xiv + 401;

THE LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE.

THE issue of a pamphlet describing the course of study for the Diploma in Public Health arranged by the authorities of the London School of Hygiene and Tropical Medicine for 1929–30 is a reminder that the coming session will find in full activity another centre of medical teaching and research in London. Several years have passed since the munificent gift of the Rockefeller Foundation made it possible to realize the ideal of the Athlone Committee, to found an imperial school of hygiene and tropical medicine. The magnificent building which H.R.H. the Prince of Wales will open in July, and the reputations of the men who have been appointed to the various chairs, are earnest that the Senate of the University and the Board of Management of the School have used the time well. An account of the progress of the new organization, with a view of the building, was given in our issue of December 8th, 1928 (p. 1045).

But even a well-equipped building and an intellectually distinguished staff will not ensure the success of a teaching institution. Still more important is a real sympathy between teachers and students, a genuine *esprit de corps*. Whether the soil of Keppel Street is favourable for the growth of this tender plant time will show; a perusal of the course of study for the Diploma in Public Health at least convinces us that the staff of the school have overcome one serious danger. The very eminence attained as research workers by the directors of the various divisions in which the school is organized might well have tempted them to exaggerate the importance of their own fields of work, and to forget that they were training future public health officers, not embryo specialists in bacteriology, statistics, or chemistry. Although the demands made upon the student's time and attention are large (290 hours of instruction in bacteriology—including medical entomology—chemistry, physics, meteorology, and climatology, and at least 170 hours in hygiene, public health administration, epidemiology, and vital statistics), pains have been taken to harmonize the different parts of the curriculum. The student will not be set to hard labour in a succession of prisons labelled "Bacteriology," "Chemistry," "Vital Statistics," and so on, but will be shown how the methods of investigation of these various disciplines may be brought to bear upon the problems of etiology and prevention, to attempt to solve which will be his lifework. "The aim of those responsible for drawing up the curriculum has been to present the teaching in a logical sequence, and to co-ordinate the teaching of the different departments mainly concerned." A course of education planned in that spirit carries within itself a better guarantee of success than even fine laboratories and eminent teachers can offer. As we said six years ago,[1] "the task before Dr. Balfour and his future colleagues is not a light one: they do not inherit the prestige of a long series of illustrious predecessors; they have behind them no tradition—they themselves must create what shall become a tradition."

No wise man would prophesy the success of any school; the psychological imponderables are too many. But, so far as human foresight reaches, the future of the London School of Hygiene and Tropical Medicine is promising. The highest duty of the school is to raise the standard of scientific education, to convince men and women who should have outgrown the dogmatic stage of teaching that the profession they have chosen offers as many opportunities for research and requires as much intellectual discipline as the work of any "pure" scientists. Displays of intellectual fireworks please adolescents, but where students as well as professors are adult, intellectual honesty and mutual comprehension are much more important qualities than even brilliance. That is the spirit of the programme. The successors, now perhaps undergraduates, of the present teaching staff have, we believe, a good prospect of enjoying the advantage of a high tradition which the work of this generation is about to establish.

[1] *British Medical Journal*, November 3rd, 1923, p. 825.

THE ETIOLOGY AND PROPHYLAXIS OF INFLUENZA.

IT is a matter for surprise to the layman that the causation of a disease of such manifest social importance as influenza, which has swept the world with devastating epidemics on several occasions, should still remain obscure. He is even inclined, being ignorant of the difficulties of the problem or unable to appreciate them, to be a little contemptuous of medical science because of its inability to find a solution, and sympathy with his point of view is not altogether unknown in the medical profession. Yet in a recent addition to the monographs of the Pasteur Institute Dr. Dujarric de la Rivière, writing on the etiology of influenza, finds it necessary to close an excellent critical survey[1] of the available knowledge with the following words: "Le chapitre sur l'étiologie de la grippe, déjà riche en travaux intéressants, reste ouvert à l'activité des chercheurs."

There are several claimants to the role of etiological agent. Is influenza due to the bacillus of Pfeiffer, to the filter-passing organism, *Bacterium pneumosintes*, of Olitsky and Gates, or to a member of the so-called ultra-microscopic viruses, as the work of Gibson, Bowman, and Connor, of Nicolle and Lebailly, of Ishiwara, and of Gordon would suggest? Probably the last of these three alternatives has the most adherents, but the question cannot readily be put to the test of experiment owing to the lack of a suitable experimental animal. Man alone would appear to be susceptible to influenza, but experiments carried out on human volunteers have been few in number and inconclusive. These experiments are further open to the criticism that they were made with a spontaneously susceptible animal in the midst of epidemics. For experimental investigations on human beings to be of any value it would be necessary to recruit volunteers prior to an expected epidemic, and to house them temporarily, together with the team of investigators, in some isolated part of the country, where, cut off from their fellows, they could be observed and preparations made for experimentation when the epidemic appeared. This may appear a somewhat fantastic scheme, and probably difficult of realization, but without such elaborate precautions experiments on man are bound to remain inconclusive.

While still ignorant of the etiology of influenza, and therefore not in possession of a method of specific prophylactic immunization, what can be done to diminish the ravages of this disease? Dujarric de la Rivière discusses the possible measures, the majority of which have been debated in medical journals, and even in the lay press, during recent epidemics. The individual may lessen his chance of contracting influenza by keeping up his general bodily resistance,

[1] *Etiologie et Prophylaxie de la Grippe.* Par R. Dujarric de la Rivière. Paris: Masson et Cie. 1929. (Med. 8vo, pp. 103; 15 plates, 6 figures. 32 fr.)

observing simple hygienic precautions (such as spraying the nose and throat with some mild antiseptic solution), personal cleanliness, and avoiding as far as possible ill-ventilated rooms, particularly where large numbers of people are congregated. The social measures may be summed up in the dictum: isolate affected individuals at the earliest possible moment of infection. Dujarric de la Rivière would like to see a skeleton service of hospitalization and mobile laboratories organized in readiness for mobilization as soon as an epidemic makes its appearance. Though ideal, it may be questioned whether such a scheme would not be too costly to put into practice. Much, however, might be done in this direction by educating the public and pointing out to them the necessity for isolating themselves in their own homes as soon as symptoms of influenza appear.

PARLIAMENTARY CANDIDATES AND ANIMAL EXPERIMENT.

IF an ordinary citizen is opposed to vivisection it is not a matter of great moment. He is not called upon to carry out experiments on animals, and when he is sick there is no likelihood of his failing to consult a doctor equipped with knowledge and skill and apparatus gained as the result of such experiments. It is more than probable that the motives underlying his beliefs are beyond reproach—a love of animals and of humanity, and a horror of wanton cruelty—and that he has been driven to hold them by a propaganda which represents vivisection as the *mutilation* of agonized unanaesthetized animals, carried out by sadistic persons revelling in the infliction of pain. We may, and do, deplore a propaganda which wilfully subjects sensitive persons to unnecessary suffering; we may, out of a love for truth and intellectual honesty, deplore the dissemination of error on any matter, especially one that so vitally affects the well-being of the community; but it is impossible to ignore the fact that the greater part of the propaganda of antivivisectionists reaches only those who prefer to regard the calm, unhurried *scientist in his* laboratory as a fiend, *and who deliberately* shut out knowledge that *would represent* him otherwise. When, however, *an individual* who aspires to legislate on his *country's behalf goes* to the trouble of announcing in his *election address* that he is "in utter opposition to vivi*section and all forms* of cruelty to animals" one may take it that he is not merely assuring the electorate that he personally would not undertake experiments on animals, but is seeking from them a mandate to prevent others from doing so. His personal inconsistencies are not our concern; we may assume that if he had to seek the services of a doctor he would not first enjoin him to put out of his mind all the knowledge he may have gained directly or indirectly through experiments on animals. "No doctor," said Professor C. Lovatt Evans in his presidential address delivered in 1928 before the Section of Physiology of the British Association, "can use a stethoscope, feel a pulse, take a blood pressure, administer a hypodermic, give an anaesthetic or a transfusion, perform any modern operations, or indeed take any steps in diagnosis, prognosis, or treatment, without utilizing at every turn knowledge derived from the results of animal experimentation and obtainable in no other way." We find it hard to believe that the antivivisectionist candidate for parliamentary honours would refuse an anaesthetic merely on the ground that its administration has been made safe and pleasant as a result of experiments on animals, or that he would, on similar grounds, refuse to avail himself of the advantages of an aseptic technique, or of an operation planned in accordance with the physiological knowledge such experiments have given us. It is improbable that he would forgo, after the operation, the relief from pain afforded by an injection of morphine, or that if he were suffering from surgical shock he would refuse the injection of saline. It is more than likely that he does not forbid the presence of vitamin-containing foods on his table because our knowledge of the action of vitamins and of the methods and indications for their administration has been gained in a manner he cannot approve; if he had diabetes he would not refuse insulin; he would take the Minot-Murphy liver diet if he had pernicious anaemia; and—dare we say it?—he would not advise any of his constituents to refuse the diagnostic aid of the Wassermann reaction or treatment by salvarsan should the voter be so unfortunate as to become infected with syphilis. These inconsistencies, let us repeat, are unimportant, except, perhaps, in so far as they are instrumental in keeping the candidate and his family alive and healthy. We are, however, deeply concerned with the danger that would accrue to the public health and to the future of medical research if these views on animal experiment were made effective in legislation. The British Medical Association seeks no pledge on the subject from Parliamentary candidates; it asks them merely not to be driven by interested bodies to promise their vote on one side or the other, but to hold themselves free when the matter comes before the House to be guided entirely by the facts brought to their notice and the arguments they hear in the course of debate.

AMBLYOPIA AND THE ARTIFICIAL SILK INDUSTRY.

IN the early days of vulcanization of rubber by the "Parkes" or "cold cure" process—dipping the article into a solution of sulphur chloride dissolved in carbon bisulphide—all those so engaged suffered from its harmful effects; and very serious they were—headache, paralysis especially of the leg muscles, mental hebetude, impotence acute mania, and not infrequently amblyopia. Laudenheimer in 1899[1] published the histories of fifty cases of mania in rubber workers. Of the first three cases described in Great Britain by A. Bruce[2] two suffered from amblyopia. Nettleship[3] described a similar case in 1885. So prominent indeed, did this symptom become that the Ophthalmological Society appointed a committee to investigate the action of the vapour of carbon bisulphide and sulphur chloride on the sight and health. This committee tabulated twenty-four cases, in five of which there was little or no improvement even after giving up the work. Many other references could be given. A story was current in Salford about 1899 of a maniacal rubber worker rushing about the factory brandishing a carving knife. Imagine the effect of this on two hundred factory girls. The Dangerous Trades Committee which reported in 1896 recommended special rules, the principal of which were: (1) downward exhaust ventilation, the vapour being more than twice as heavy as air; (2) enclosed machines for waterproofing cloth; (3) no spells of work to last more than two and a half hours without a break of one and a half hours; (4) monthly medical examination of the workers by the certifying surgeon. So successful were the special rules drawn up on these lines that little more was heard of CS_2 until new uses were found for it, and especially in the artificial silk industry by the viscose process. Stress has been laid on the severity of the symptoms in the absence of scrupulous attention to detail in precautionary measures. It is disquieting to hear of a case of amblyopia contracted in an artificial silk factory, and to read, in a recent report of the Chief Inspector of

[1] *Die Schwefelkohlenstoffvergiftungen der Gummi Arbeiter unter besonderer Berücksichtigung der psychischen und nervosen Störungen und der Gewerbehygiene.* Leipzig, 1899.
[2] Chronic Poisoning by Carbon Bisulphide. *Trans. Med.-Chir. Soc. Edin.*, 1883-84, pp. 145-153.
[3] *A Case of Amblyopia with Partial Optic Atrophy and General Nervous Depression and Emaciation caused by the Vapour of Carbon Bisulphide; Partial Recovery. Trans. Ophthal. Soc. United Kingdom*, 1885.

Factories, of a severe case involving "headache, vomiting, delirium, loss of muscular power, and almost complete loss of sensation." The trouble occurs in what is called the "churn" room, where the alkali-cellulose is treated with carbon bisulphide in a hermetically sealed mixer or churn. After the process is stopped at the desired point a negative pressure is maintained in order to remove the vapour. The workman, however, is then compelled to put his head inside the churn to remove the orange-coloured sticky mass. Few workers in the churn room are free from the slighter symptoms, attributable to carbon bisulphide; nor is this surprising, seeing that 0.3 part per 10,000 of air will produce them. Efforts should be made to find a substitute for carbon bisulphide. This, however, is not the only risk run in the artificial silk industry. Extreme discomfort is caused by the sharp pain, photophobia, and conjunctivitis set up by traces of sulphuretted hydrogen gas generated at the spinning troughs. The gas may not be present in a proportion greater than 1 part in 10,000 of air, but such small amounts are just those to cause the distressing symptoms mentioned. We recall that in the change over from the manufacture of yellow phosphorus to the sesquisulphide a manager of a works confessed that his life was made miserable to him by incessant conjunctivitis until he had placed every bin for the storage of the stuff under a negative pressure. Another manager of a chemical works in those days was visiting weekly (without improvement) an ophthalmic surgeon for chronic conjunctivitis limited to one eye. This eye it was that he applied periodically to the peep-hole of a vat, otherwise closed in, in which H_2S gas was given off. The artificial silk industry starts with a tremendous advantage in the experience already gained as to the effects of the toxic agents used or evolved. The day in, day out exposure to them by the workpeople should never be forgotten.

RECURRENT SCARLET FEVER.

In this week's issue (p. 986) Dr. W. H. Kelleher reports an interesting case of a patient who, between the ages of 13 and 28, had five apparently definite attacks of scarlet fever, for which she was detained in various Metropolitan Asylums Board fever hospitals for periods never less than five nor more than nine weeks. The description given of each attack is sufficiently convincing to justify the diagnosis of scarlet fever on each occasion. Cases of the kind must be extremely rare, as not only are most authorities agreed that second attacks of scarlet fever are uncommon, but it is also exceptional for the diagnosis of repeated attacks in the same patient to be confirmed by experts in the diagnosis of scarlet fever, as occurred in Dr. Kelleher's case. Although probably more frequent than a relapse—that is, a recurrence of the characteristic symptoms of the disease while the patient is still under treatment—a second attack of scarlet fever some months or years after the first is not a common event, even if it is less exceptional than a second attack of certain other acute infections. Why is it that some infectious diseases, such as measles, small-pox, or typhus, are rarely followed by second attacks, whereas other infections, such as influenza, erysipelas, and gonorrhoea, are particularly liable to recur on exposure to fresh infection? It is difficult to account for the occurrence of such cases, and it is little more than a confession of ignorance to say that most recurrent attacks are due to a constitutional inability to form antibodies to the disease in question. In a recent article on relapses in scarlet fever Burton and Balmain[1] have pointed out that there appears to be a definite class of individuals whose blood is unresponsive to the toxin of scarlet fever, and while such patients recover from a mild attack they are liable to a relapse or to have two or more attacks. It is noteworthy that one of their patients, who was Dick-positive after an attack of scarlet fever, and again after a relapse, was again Dick-positive when tested three weeks after active immunization with the maximum dose of scarlatinal toxin.

THE NATIONAL PHYSICAL LABORATORY.

THE National Physical Laboratory's report for the year 1928[1] is a quarto volume of close upon three hundred pages which describes in detail the work of the six departments at Teddington, where so many problems confronting science and industry are being worked out. A new building for the physics department—hitherto both scattered and cramped—is being constructed, and is to embody features noted at universities and industrial laboratories in many different countries. During the year the erection of the million-volt transformers in the high-tension building has been completed, and it is expected that this plant will prove invaluable for dealing with a number of urgent problems of electrical industry, particularly in relation to the new national electricity scheme. Representatives of the laboratory have taken part during the year in a number of important conferences directed to the establishment or maintenance of international uniformity in the standards of measurement employed for various purposes. One of the most interesting parts of this report is a statement on the various standards at the laboratory and their history. All measurements of radium made at the laboratory are referred to the British radium standard, one of the secondary standards prepared on the basis of the official standard, which belongs to the International Radium Standard Commission and is preserved at Sèvres. The secondary standard, which has been at the laboratory since 1913, was then tested by Madame Curie and others, and found to contain 21.13 mg. of anhydrous radium chloride. A correction is made periodically to allow for the decay of the radium, and the present value of the standard is taken as 20.99 mg. of radium chloride, equivalent to 15.98 mg. of radium element. The value of the radium received by the laboratory for testing last year exceeded £125,000; it included some 10 grams of radium element tested on behalf of the Australian Government, in the form of needles, tubes, and plaques to the number of 1,350. The standard of x-ray intensity employed at the laboratory is the international unit adopted by the recent Congress of Radiology at Stockholm, and to be referred to as the "röntgen" or r unit. Steps have been taken to evaluate in r units the provisional ionization standard set up some years ago in the laboratory for the routine testing of barium platinocyanide pastilles. It is stated that the co-operation of the physics department with the X-Ray and Radium Protection Committee has been actively maintained, and the assistance of the laboratory has again been sought by a number of hospitals in London and the provinces. "There are many indications," says the report, "that the publication of the recommendations of the committee, together with the facilities provided by the laboratory [for the testing of protective materials] have resulted in very marked improvements in the standard of protection attained by British makers of x-ray apparatus." Among the many branches of work undertaken by the laboratory during the year has been research on acoustics of buildings.

PLAY CURES.

IT has long been recognized that amusement in the widest sense of the word has its value in the restoration of the invalid to normal health. The very word "recreation," which has been used in this sense for five hundred years, implies as much, and all therapeutists, in varying degree, have employed both mental and physical games in their

lists of remedies. The children of the last century were familiar with Dr. Watts's verses on the "little busy bee," with its recommendation of "books and work and healthful play." It is, however, to America that since the war we have looked for the systematic scientific application of play in the building up of the moral and physical strength of the sick and injured. At the great convalescent hospital of the Burke Foundation at White Plains in New York State, Dr. Frederic Brush, who is its medical director, has made a serious study of the application of play to purposes of physical improvement. In a pamphlet on "Recreational therapy in convalescence and allied subnormal health conditions" (issued through the Sturgis Fund) he briefly sets forth the principles on which amusements are organized at White Plains. For fourteen years, he says, the play cure has been made predominant at the Burke Foundation's country recuperative institution in addition to occupational therapy. Golf stands at the head of his list of games, and in order to bring it within the scope of all, special short and easy courses have been laid out, the simplest of which have holes from 10 to 70 yards in length, the whole course being not more than 600 yards in length and without any steep gradients. He considers that "As an exercise in these substandard health states it well-nigh fulfils the ideal—comprising outdoor walking and exercise of the entire body." So highly does he rate the game that after consultation with other physicians—particularly Dr. J. H. McCardy, head of the School of Physical Education at Springfield College—it was decided to start an elaborate research into the effect of golf upon convalescents. This work was entrusted to Dr. Peter V. Karpovich of Springfield, whose report, with many tabular illustrations, was published last year (A Study of some Physiological Effects of Golf, *American Physical Education Review*, November, 1928, vol. xxxiii, No. 9). There were 120 people examined at the Burke Foundation, 90 of them thoroughly. These latter were 16 men and 26 women golfers, 40 men patients and 8 women patients, 20 of these being cardiac cases. The details are far too voluminous to be quoted here. The results did not essentially differ from other recorded observations of the effects of muscular and nervous effort on the pulse rate and blood pressure, and the conclusions arrived at strongly supported Dr. Brush's opinion of the value of the game, although Dr. Karpovich records his belief that disgust and anger, which are said to increase the blood pressure, characterize the most common mood among golfers. If this belief is justified, surely the effects of playing golf are not wholly beneficial. Dr. Brush says: "To appreciate its growing importance in the field to [*sic*] recreational therapy one must acknowledge that the game of golf is rapidly advancing toward the first sports place in Western civilization." Golf has hitherto been, in both England and America, only within the reach of the well-to-do, and Dr. Brush finds that his less wealthy patients take on the game with scarcely *any urging*, and with a feeling of having somehow advanced socially as well as physically. This feeling may be called snobbish, but yet may have its value in recreational therapy. Walking in parties and combined with nature study, bowls, quoits, horseshoe throwing, snowballing, and tobogganing, and, indeed, every *game has* its place in Dr. Brush's armamentarium. However crippled a patient may be, a beginning can be made with the help of others. Thus a patient on crutches may begin to play golf or bowls by getting another to do the stooping for him. The claim is made: "We store away more discarded crutches than the most popular religious curative shrine." When the weather does not allow outdoor games, all manner of indoor amusements are utilized; even smoking in moderation and eating sweets are included in the list. *Dancing*, both out of doors and in, occupies a high position. Ballroom dancing nowadays is not necessarily a vigorous exercise, and a beginning can be made by quite severely crippled persons with the help of a more active partner. In this, as in most other recreations, Dr. Brush rates high the value of intermingling of the sexes, "which results also in the holding of a considerable percentage of the younger patients to completion of convalescence who would otherwise become restless and leave." Gambling on competitions is sternly forbidden; it is said to have had a wholly bad effect on convalescence. No doubt there is great value in many of Dr. Brush's recommendations, which, it must be remembered, are the outcome of years of observation and experiment. In the past many a convalescent, after the first lassitude was over, must have felt bored and weary for want of occupation, but the greatest tact must be employed by those in control if the patient is to escape the feeling that instead of taking part in a voluntary game he is asked to perform an irksome duty. It has sometimes seemed to us that the accounts of mass training and investigations in American universities showed an amount of docility and a readiness to submit to discipline which would be found wanting in anything like the same degree in this country.

OPHTHALMIC HOSPITAL IN JERUSALEM.

IT is satisfactory to learn that the work of the Ophthalmic Hospital in Jerusalem continues to extend, and that the equipment has been improved in several respects. Although there has been a considerable increase in the numbers of new cases and total consultations, fewer in-patients were admitted during 1928, owing to the fact that a large number of intraocular cases have been dealt with, necessitating a longer stay for each. In his annual report for 1928 the warden, Lieut.-Colonel J. C. Strathearn, M.D., attributes the "record" number of patients dealt with during this year to the fact that, for the first time in the history of the hospital, an open and unrestricted clinic has been conducted on six days in the week, thanks to additional voluntary surgical assistance which has been obtained temporarily. Remarkably severe ophthalmia epidemics have been occurring in Egypt and Palestine during the last few years, and have had much to do with the rise in the number of cases of blindness in both countries. The warden remarks that these epidemics have been increasingly severe since 1926, coinciding with shortage of rains in the winters. The incidence of trachoma has also risen, possibly owing to the large number of Moslems attending the hospital as compared with the Jews, who are the least infected of the local population. The warden believes that an additional factor is the spread of trachoma by serious epidemics of acute conjunctivitis such as those of the last three years. The clinic scheme in connexion with the hospital—to which previous reference has been made in these columns—continues to work well. Unfortunately visits for supervision could only be paid to these valuable institutions once in the year; it is hoped that in 1929 each clinic will be visited quarterly, thus enabling even more effective treatment to be given. At present six of these clinics, which were instituted by the Palestine Government, are in operation at Acre, Beersheba, Gaza, Nablus, Ramleh and Tulkarem respectively. Over 18,000 new cases were seen at them, and nearly 150,000 consultations were given. Of the 2,500 operations performed at the clinics the majority were for trichiasis, thus reducing a little the pressure of these cases on the hospital in Jerusalem. Alterations and improvements in the existing hospital building have been effected, and a new south block is to be built, designed to receive on the upper floor paying patients, and to increase the general accommodation for poorer patients. This institution, we may remind our readers, is owned and managed by the Order of St. John.

INDUSTRIAL CONDITIONS OF THE DEAF AND DUMB.

THE National Institute for the Deaf have issued the report of an investigation into the industrial conditions of the deaf and dumb.[1] It is accepted that in the United Kingdom there are some 40,000 persons deaf from birth or early infancy—that is, about 1 per 1,000 of the population. This figure takes no account of those who become deaf or hard of hearing in youth or adult life. Under the Education Act of 1895 the training of the youthful deaf has greatly improved. The cost is great; but it is encouraging to note that modern methods have shown that linguistic and cultural retardation does not represent a corresponding backwardness in general intelligence, for in actual performance tests the deaf and dumb have been found to compare favourably with normal children of similar ages. But, for all that, the linguistic difficulty, even when overcome by artificially acquired speech, is very great, and leaves the deaf at a disadvantage. Viscount Gage, speaking for the Government in the House of Lords in 1928, said: "The Board of Education, so far as its information goes, is under the impression that the deaf child who has attended a special school up to the age of 16 is able to obtain and retain reasonably good and remunerative employment." The report indicates that this is too hopeful a view. The school "leaver" is usually *qualified* for employment, but there is extreme difficulty in placing him in it; between 30 and 50 per cent. of leavers during the last three years had not been placed. Modern industry requires speed in work and complete understanding between fellow workers. Further, the Trades Boards' requirement of payments according to age in several skilled occupations operates adversely to the deaf. At 16 the normal youth has had two years of training when the deaf makes his start. Various Employers' Liability Acts and Workmen's Compensation Acts are often cited by employers as reasons for preferring normal workers to the deaf. Apart from trades necessitating dangerous machinery the deaf are said to be as immune to accident as those who hear, but none the less companies are inclined to demand higher premiums of insurance. Much good work is done by the after-care committees attached to elementary schools in placing leavers, but they are unable to take effective action in widely remote districts from which pupils may be drawn. The report urges that the time has come when there should be an official inquiry into the general industrial conditions of the deaf and dumb with a view to the amelioration or removal of the difficulties from which they now suffer. The latest returns, gathered unofficially, show that in the case of men workers some 40 per cent. are either not employed or only casually occupied; and in the case of women some 47 per cent. are in a similar unsatisfactory position. The cases of elderly deaf and dumb persons who become unemployed are especially hard, because advancing age, added to deafness, makes finding fresh employment almost impossible. It is believed that this constitutes a strong claim to the lowering of the qualifying age for old age pensions for those so afflicted.

INTERNATIONAL LEAGUE AGAINST RHEUMATISM.

SOME account of the founding of the International League against Rheumatism by the International Society of Medical Hydrology has already been given in these columns.[2] Among the activities which were proposed for the league was the publication of a periodical, and the second number of the *Acta Rheumatica* has now been issued *in statu nascendi* as a loosely bound collection of typescript papers. This publication contains reports of national meetings on the subject of rheumatism, such as that of the American committee, held in Boston in October, 1928, and the statutes drawn up for a German association and for a Belgian association. As was mentioned in the first number of the *Acta Rheumatica*, the scheme of inquiry of the British Ministry of Health has been adopted, and suggested standard forms of inquiry for use in different clinics throughout the world are set out so that a real international methodical study of the disease will be possible as material is collected. The preliminary programme for the International Congress on Rheumatism, which is to be held at Budapest in October, 1929, is also included. Two main subjects will be discussed: the relation between acute and chronic rheumatism in the various countries and the significance of serological and blood examinations in rheumatic diseases. The *Acta* also contains a list of all books, papers, etc., dealing with rheumatism received or reviewed by the bureau during the first quarter of 1929.

RARE MEDICAL WORKS.

A SMALL number of very old and rare medical works are included in Messrs. Sotheby's sale during the week commencing June 3rd, mainly on June 5th. One is a manuscript on vellum, believed from certain peculiarities in the spelling to have been written in the North of England, and containing a note of ownership by one Richard Burton of Lancaster, vicar of that city from 1466 onwards. It is a treatise on the urine in its medical significance, and the opening sentences show the quaint character of the document: "Uryne ys as mekyll to say yn ynglische as on in ye Reynys. Reynys frenche Renes latyn lendys in englysche yf you wyttyn urine by what ar in ye reynys. . . ." Another is a French version, dated 1569, of Vesalius's *Anatomy*, edited by Jacques Grevin and published in Paris by André Wechel. The auctioneers observe that the plates are the same as those in the 1545 edition issued by Thomas Gemini, London, and suggest that the identical copperplates were probably sold to the Paris publisher. Just as interesting for its original fine vellum binding as for its contents is a manuscript *Compendium Medicinæ*, probably to be ascribed to 1494. The first part contains the general principles of medicine, the second deals with remedies made from herbs and from animals, while the third deals with special branches of medicine, beginning with fevers and ending with the diseases and affections of the skin. There are also a number of very old books and MSS. dealing with alchemy in the same sale.

FERRIER MEMORIAL LECTURE.

THE contributors to a fund to commemorate the late Sir David Ferrier and his pioneer work upon the functions of the brain requested the Council of the Royal Society to accept the sum of £1,000 in trust for the institution of a David Ferrier Lecture. The Council, in accepting the trust, decided that the lecture should be given triennially on "a subject relating to the advancement of natural knowledge of the structure and function of the nervous system." The first David Ferrier Lecture will be delivered by Sir Charles Sherrington, O.M., G.B.E., on Thursday, June 20th, at the rooms of the Royal Society, Burlington House, at 4.30 p.m. The title of the lecture will be "Some functional problems attaching to convergence."

LORD BEAVERBROOK, in a letter to the dean of St. Mary's Hospital Medical School, has announced that, in order to assist in the future welfare of the school, he is prepared to undertake, for a period of seven years from May 25th, to contribute the annual sum of £9,000. The effect of this munificent gift will be to augment the funds of the school by a total amount of £63,000.

THE Morison Lectures before the Royal College of Physicians of Edinburgh will be given by Dr. R. Dods Brown on June 3rd, 5th, and 7th at 5 p.m.; their title is "Some observations on the treatment of mental diseases."

[1] The Industrial Conditions of the Deaf and Dumb. Report of an Inquiry by the National Institute for the Deaf. London, 1929. Price 6d. 2, Bloomsbury Street, W.C.1.

[2] *British Medical Journal*, August 18th, 1928, p. 319.

A REGISTER OF BIOPHYSICAL ASSISTANTS.

THE British Medical Association has long given serious consideration to the problem of protecting the public from the untrained and unqualified physiotherapist. It will be recalled that on July 20th, 1928, at Cardiff, the Representative Body of the Association, in discussing the risks involved in the unskilled administration of actinotherapy, recommended that immediate steps be taken to place this form of treatment under the control of the medical profession, and indicated the general lines along which such control should be exercised. In the form of a resolution it expressed the opinion that suitable courses of training should be organized under medical direction for persons who wished to administer treatment by electricity and radiation; that persons who had satisfactorily followed such a course should be entitled to have their names entered on an approved register; that a condition for inclusion on the register should be abstention from the treatment of any patient except on the responsibility and under the general supervision of registered medical practitioners; and that persons requiring electrical or radiation treatment should be referred only to persons so registered.

Following on this resolution the Council of the Association appointed a special committee composed of members of the Science and Medico-Political Committees to consider in detail the method or methods by which these recommendations could be made effective, and at a meeting of the Council held on December 12th, 1928, Mr. H. S. Souttar, on behalf of this committee, expressed the opinion that the only method which held out any immediate prospect of success was by voluntary action, probably in the form of the institution by a recognized authority of a diploma qualifying lay persons as dispensers of physiotherapeutic treatment. He stated that both the British Institute of Radiology and the Chartered Society of Massage and Medical Gymnastics had approved the principles underlying the Association's proposal.

When the Council met again on February 6th, 1929, it was announced that, on the proposal of Professor W. E. Dixon (a member of the committee), informal conversations had been held with representatives of the Society of Apothecaries of London, which had agreed to set up a standard to which persons practising physiotherapeutic treatment should attain, and to establish a diploma and a register on lines conforming to those laid down in the resolution of the Representative Body. The Council agreed that Dr. C. B. Heald should be nominated as the Association's representative on the standing committee of the Society of Apothecaries which, it was understood, was being constituted to administer the scheme. The committee has met on a number of occasions, and the first-fruits of its deliberations have recently been issued by the Society in the form of a pamphlet embodying regulations for admission to the roll of registered biophysical assistants.

Training and Examination.

An approved course of training, the committee states, will be necessary for all who desire to be placed on the roll, and all applicants after May 31st, 1930, will be required to pass an examination. In order, however, that injury should not be done to those persons who are already qualified and are engaged in administering treatment by electricity and radiation, it is proposed that admission may also be obtained by those applying not later than May 31st, 1930, who produce satisfactory evidence of experience in the following subjects: ultra-violet radiation, light and heat, high-frequency current, including diathermy, faradism, direct and sinusoidal currents. This evidence should consist of (*a*) not less than two years' supervised and practical experience at a teaching hospital or at any approved institution with a special physiotherapy department under a specially appointed medical officer, or (*b*) a certificate signed by two medical practitioners who are on the senior medical staff of a voluntary hospital, stating that from their personal knowledge they know that the applicant has had not less than three years' practical experience in the therapeutic administration of each of the above-mentioned forms of treatment.

If an applicant who applies before May 31st, 1930, has not had experience in one or more of the subjects, the Society is prepared to consider certificates from a medical officer in charge of an approved institution, stating the course of training the applicant has undergone. The Society may, during the period ending May 31st, 1930, require any applicant to submit himself or herself to an oral and practical examination in any of the subjects.

Applicants for registration will be required to undertake that they will not (*a*) treat any patient except under the direction and control of a registered medical practitioner; (*b*) advertise in a professional sense except in the recognized medical and nursing papers, or sell goods to patients in a professional capacity or accept secret commissions on the sale of goods; (*c*) act in such a manner as in the opinion of the Society is considered derogatory to the honour of their profession. The registration fee will be two guineas, and there will be an additional annual payment of five shillings for continued inclusion in the register.

Registered persons will be designated biophysical assistants, and be entitled to use the registered letters B.P.A. They will receive from the Society of Apothecaries a certificate of registration and a book containing the regulations. In concert with the British Medical Association, which recognized from the first that the scheme would depend for its success on the co-operation of the medical profession, the Society under takes to advise medical men by every means in its power to employ only registered biophysical assistants in the treatmen of their cases. The register will be circulated widely each yea to registered medical practitioners, to medical and publ libraries, and to public medical officers, so that it may b available for reference in every district of the country. A annual conference of biophysical assistants will be arrange at Apothecaries' Hall, Blackfriars, for professional and soci purposes.

Certificate of Registration.

The certificate of registration, to be issued over the signatu of the Registrar, reads as follows:

"Know all men by these presents that.....has be approved by L. D. Bailey, M.C., Major-General D. J. Colli C.B., C.M.G., M.D., W. E. Dixon, F.R.S., M.D., C. B. Hea C.B.E., M.D., M.R.C.P., F. D. Howitt, M.D., M.R.C.P., J. M B.A., M.B., B.Ch., Lieut.-Colonel C. Sammann, Master of Apot caries' Society, and Sir William Hale-White, K.B.E., M. F.R.C.P., the Committee appointed by the Master and Ward of the Society of Apothecaries, as a fit and proper person reason of his/her knowledge and skill to be placed on the of Biophysical Assistants. In Testimony whereof the Regis of the said Society by the Authority of the Master and Ward has hereto set his hand."

Applications for registration should be made to the Regist Society of Apothecaries, Water Lane, Blackfriars, E.C.4.

INTER-STATE POST-GRADUATE ASSEMBI

SIR JOHN BLAND-SUTTON'S INAUGURAL ADDRESS.

THE party of between fifty and sixty members of Inter-State Post-Graduate Assembly of North Am which has been visiting London gathered for the fi three morning sessions at the House of the Royal Soci Medicine on May 27th. The names of the lecture this and the two subsequent mornings and the other of the programme were announced in our last issue (p

Sir JOHN BLAND-SUTTON, Bt., in opening the proce and welcoming the visitors, recalled that in the autu 1927 he attended an excellent meeting of the As in Kansas City, and contributed to the proceeding realized then the great importance of this organi It had never been so necessary as it was at presen

men in active practice should keep themselves abreast of the arts and sciences ancillary to modern medicine. The proud position of surgery to-day was in no small degree due to discoveries in chemistry which placed in the hands of surgeons the power to induce anaesthesia. Then came the conquest of sepsis, which raised surgery from a mere craft into a beneficent art. Improvements in the microscope had enabled the minute organisms which provoked disease to be discerned, and there followed the astounding revelation that the germs of disease and death were hidden in the smallest of living things, and conveyed by unsuspected carriers. Another noteworthy advance was the invention of special instruments for examination, which had laid the foundation of many of the specialties. Among these instruments were the ophthalmoscope and the laryngoscope; the inventors of both were non-medical men, Helmholtz, the philosopher, and Manuel Garcia, the singer. It was said that when von Graefe first saw the fundus of the human eye with the ophthalmoscope he flushed with excitement and said, "Helmholtz has unfolded for us a new world." The speaker related how he himself went to Vienna in order to become facile with the ophthalmoscope, because he realized that that instrument was to be of diagnostic value for diseases arising elsewhere in the body than in the eye. There was now no hollow organ in the body into which the incandescent lamp could not throw its light. The x rays, again, had made the human body diaphanous to surgeon and physician alike. No surgeon who valued his reputation or his patient's welfare would trust entirely to his own tactile sense in detecting fractures. He would have recourse to the x-ray picture, which, incidentally, could be studied by the patient himself, by his friends, or, worse still, by his solicitor. Improvements in optical glass were now so great that he felt sure it would be possible soon to see the living cell elements of the body—to see the red corpuscles whirling through the capillaries as in the familiar experiment on the circulation in the foot of the frog. When he was a boy, sixty years ago, a kind aunt made him a present of a microscope, and he was much interested in the red corpuscles, because there was at that time a good deal of argument among physiologists as to their shape. To-day, when reports were received from the laboratory with regard to the patient's blood, there were recognized as many varieties in the red corpuscles as there were races of men. But with all their knowledge and skill, physiologists could not yet say how long the red corpuscle lived absorbing and carrying oxygen. Then he bade them think of phagocytosis, again a non-medical discovery. Metchnikoff's experiments with starfish larvae at Messina had laid the foundation of the study of defensive cell mechanism. At the time that discovery was published he (Sir John Bland-Sutton) was investigating the dead bodies of animals at the Zoological Gardens, and when it became his duty to deliver some lectures at the Royal College of Surgeons he ventured to describe inflammation as a warfare between the cells and the bacteria. That was forty years ago, but in that very room on the morrow Dr. R. G. Canti would show one of the most striking films he had ever seen, illustrating the combat between bacteria and leucocytes. Sir John Bland-Sutton believed that by a combination of x rays and magnifying apparatus it would be possible some day to see the exotic fauna of the blood—to see floating through the capillaries, jostling the red cells, the spirochaetes, the trypanosomes, the filaria. Indeed, he believed an acute observer had succeeded in seeing the guinea-worm wriggling through the subcutaneous tissue, like an eel creeping through the grass meadows from one stream to another.

"This Inter-State Assembly," said Sir John Bland-Sutton, "meets once a year, and that will give you all opportunities of hearing masters of medicine describe progress and new procedures. It will enable you to hear surgeons describe their own method of attack. Surgery is progressing at such a rate to-day that textbooks on operative surgery really become like time-tables, which are useful only for a season. This Assembly will do a great good by keeping you informed of these almost kaleidoscopic changes which are taking place in our profession."

The ordinary business of the session then proceeded.

Nova et Vetera.

SICK AND WOUNDED IN THE ARMIES OF CROMWELL AND CUMBERLAND.

NEARLY thirty years have passed since Professor C. H. Firth delivered his Ford Lectures at Oxford on Cromwell's army. The great war has since eclipsed the doings of the small forces of the seventeenth century, but the recent publication of Sir John Fortescue's *Historical and Military Essays* reminds us once more of the lot of the sick or wounded soldier in the last war waged in this country. Professor Firth gave a very full account of the medical organization in the armies of the Civil War and the Commonwealth.

No doubt the medical arrangements at the beginning of the Civil War were rather haphazard, but it was to be expected that in the better ordering of Cromwell's new model army the medical department would share with the combatant forces in the improvement. When Cromwell set out for Scotland in 1650 the army was provided with regimental surgeons and what may be called physicians and surgeons on the general's staff. Each regimental surgeon was allowed £15 to pay for a chest of drugs and instruments, and £10 for a horse to carry it. His pay was six shillings a day. In the list of the staff of the new model army are the names of four medical officers, and the armies in Ireland and in Scotland each had a physician-general, a surgeon-general, and an apothecary-general, which posts were maintained after the Restoration. Of course, there were no stretcher-bearers or hospital orderlies for many years after the '45. So late as the battle of the Alma in 1854 only the bandsmen were allowed to attend to the wounded. Combatants were strictly forbidden to do so, lest soldiers with little stomach for the fight should make assistance to a wounded officer an excuse for retirement out of fire. Professor Firth, however, shows that the idea of an ambulance corps is very old. He quotes the following passage from the *Stratioticon* of Digges, written in the sixteenth century.

> "It were convenient to appointe certaine carriages and men, of purpose to give their attendance in every skirmishe and incounter to carry away the hurt men to such place as surgions may immediately repayre unto them, whiche shall not only greatly incourage the souldior, but also cause the skirmishe to be the better maintained, when the souldiors shal not neede to leave the fielde to carry away their hurte men. These were called among the Romans 'Despotati.' And this among other laudable Romane orders have the Spaniards at this day revived and put in practice, whereby also they conceale from the enemie what losses in any skirmishe they have received."

In the Civil War (or the Great Rebellion, as it was officially called) the surgeons and men of the victorious army cared as best they could for their own wounded, and then usually leave was given to the people of the neighbourhood to do, of their charity, what they could for the enemy's wounded who were left on the field. The more fortunate among the wounded of both sides were taken into houses near by and cared for by the occupants, and claims for payment for such care were made and paid by Parliament. There is a bill in the Record Office from a civilian practitioner, one George Blagrove, for ten shillings for "curing a sore brused leg. Cut over the eye and a sore thrust through the arme, twenty shillings." This bill also includes a charge of £5 for curing the wounds of twelve cavaliers (no doubt prisoners) of whom most were "sore cut in their heads and thrust in the back."

Similarly accounts were sent in to the authorities a century later for attendance on sick soldiers left behind on the line of march. In his article "Sick Soldiers of the 'Forty-five"[1] Sir John Fortescue includes two accounts sent in by a Scottish surgeon, of which the first runs as follows:

> "David Brodie, of Elgin, for professional attendance on George Recuby, of Cobham's Dragoons [now called the Tenth Hussars]

[1] *Historical and Military Essays.* By the Hon. Sir John Fortescue, LL.D., D.Litt. Macmillan and Co., Ltd. 1928.

left in a country village dangerously ill on April 16 [1745, the very day of the battle of Culloden].

"N.B.—Any cloathes *that the man had lyes in a village called* Oldmilns; his landlady took his money out of his pocket, which she says *was only* six shillings, and says she expended it on *aqua vitae*, which I *am persuaded* hurt him."

If, as Sir John Fortescue suggests, this was a case of pneumonia, it would appear that the landlady, like the physicians of fifty years ago, regarded brandy as the only hope, while Dr. Brodie must have been 150 years before his time in dispensing with its use. In the rather similar case of Francis Hazle-Dick, Dr. Brodie's bill contains similar drugs, but there is no charge for victuals in this case. The total, including funeral, was only 17s. 6d. sterling. Both patients were blistered, but that was the common lot at that time, from which no medical case could hope to escape. Charges were low in those days and in that country, and we are not as much surprised as Sir John Fortescue to find that the inclusive charge "for hanging seven deserters" was £2 5s.

ROYAL MEDICAL BENEVOLENT FUND.

At the recent meeting of the committee fifty-one grants were made, amounting to £1,204 3s., the largest sum of money voted in any one month since the Fund was founded. It is a clear indication of the increasing number of applications for assistance which are being made to the committee.

It is the hope of the committee that financial help will never be refused to a deserving case, but to be in a position to meet the ever-increasing demand the committee urgently appeal for the support of new subscribers. Subscriptions and donations should be sent to the Honorary Treasurer, Royal Medical Benevolent Fund, 11, Chandos Street, Cavendish Square, W.1.

In addition to the grants voted above, the committee elected five beneficiaries to "Alexander Lawrence Annuities," the annuities being £70, £65, £60, £60, and £52.

The following are short notes on five of the cases helped by grants.

Widow, aged 50, of M.R.C.S., L.R.C.P. On the death of her husband, in June, 1928, the widow was left with an income of £50 a year and two daughters to educate. Her husband had served throughout the war, and during service contracted a disease which undermined his health, and which led to his death at the age of 51. The Officers' Association will contribute £30 yearly towards the school fees of one child, and the Fund has voted £40 for the school fees of the other. The widow is trying to augment her income by taking paying guests.

M.R.C.S., L.R.C.P., aged 60, is suffering from general paralysis. His wife and child of 5 are dependent on him. Private income £128 a year. Voted £40.

Daughter of L.R.C.P., aged 61, has supported herself through life as governess and companion. Of late years she nursed and kept house for a delicate married sister, who has now died, and she is left dependent on her brother-in-law, who is suffering from advanced tuberculosis. Voted emergency grant of £10 and £26 in four instalments. Two other professional charities will also co-operate and help this case, which is one of complete destitution.

Widow of L.R.C.P., aged 72, on death of her husband was left with an income of £67 a year. Voted £36.

Widow of M.R.C.S., aged 80, is very feeble and in very straitened circumstances. Since the death of her husband in 1912 she has had to use up her capital; she has now sold her last security, which realized £220, and this is all she has left to live on. Voted £36.

The Royal Medical Benevolent Fund Guild still receives many applications for clothing, especially for coats and skirts for ladies and girls holding secretarial posts, and suits for working boys. The Guild appeals for second-hand clothes and household articles. The gifts should be sent to the Secretary [illegible] gh Street, W.1.

France.

[FROM OUR OWN CORRESPONDENT.]

The B.C.G. Controversy.

THE B.C.G. controversy, to which so many refere have been made in the columns of the *British Me Journal*, is far from being closed. At a recent mee of a Paris medical society Professor Albert Calm brought forward some new statistics. He insisted such a state as immunity to tuberculosis did not exist in the adult, as Professor Marfan had shown f years ago, and that the tubercle bacillus when tre with bile was sufficiently attenuated and might used as a vaccine. He asserted that children exp to infection showed a death rate from tubercu of 15.9 per cent.: if vaccinated with B.C.G. rate fell to 3.4 per cent. According to him, cli experiments had proved that B.C.G. could not re its virulence in the organism, and that a hu being thus vaccinated at the ages of 1, 3, 7, and years should be finally immune against tubercul but this is at present no more than hypothetical, experience only can prove the case. Professor Le Lan has systematically administered B.C.G. to every infan his maternity ward at the Bouciaut Hospital. H convinced now of the value of this method, having tre thus 2,649 cases from 1926 to 1928. Dr. Weil-Hallé re mends its extension to all nurses and medical stude The Secretary of State, M. Loucheur, is organizing sy matically its adoption throughout the country, lea full liberty to doctors and midwives, the vaccine b distributed by the Pasteur Institute, where it is prepa Nevertheless, the opposition of Professor Liguières is strong, and no doubt it is serving useful purpo Pasteur, himself, would not have been Pasteur if he not had to resist fierce opposition.

Law v. Surgery.

A curious lawsuit has moved opinion in the medi world. One of our best-known surgeons, on the P Hospital staff, was asked by a hospital patient to impr the "aesthetics" of her leg. She was a couturière, her success depended on the smartness of her perso appearance. The surgeon operated, but the unexpe happened, and the result was infection, and, fina amputation. A lawsuit followed, and damages up 200,000 francs were awarded. This is a very unfortu case. There appears to be general agreement as to legality of the consequences; but the comments of magistrate have given rise to considerable feeling. based his verdict, not on any mistake by the surge whose skill is beyond suspicion, but on the fact that operation was not justified from any pathological ca But is the judge qualified to come to a conclusion with expert advice? Some time ago a surgeon lost his case won on appeal) against a patient who had had a fractu leg shortened by an inch after reparation. Supposing t spirit prevailed in court, would it not be a strong temp tion for the surgeon to abstain from any operation w there is a risk to be run? Professor J. L. Faure, in inaugural speech at the Congress of Surgery two years a drew attention to this new form of antagonism between and medicine. The case has stirred opinion to such extent that the General Medical Association of Fra has decided to follow up the case, and has asked ev medical society to join in, so that cosmetic surgery sho not be barred by law. The case is going to appeal bef long.

A Court of Medical Ethics.

A few recent scandals have aroused medical opin at large to protest that we are unable to carry o our own policy against undesirable members of the p fession. It is proposed that, just as with barristers, *ordre des médecins* should be created; this would allo to erase from the register men whom we do not esteem be qualified to practise medicine. Up to now the prop has met with strong opposition. But times are chang

rapidly, and the new law of social medicine is manufacturing quite a new type of doctors, who will be best guarded against temptation if they feel that their very practice may be controlled by their colleagues. The drawback to this new departure is that this *ordre des médecins* must act with the most liberal spirit, and must never be biased as regards new therapeutic measures which may seem heterodox or antiscientific. Perhaps the proposals will include restrictions so as to apply solely to social medicine. There is so little liberty left nowadays that there must still remain some free land where medicine may remain a liberal profession. And, after all, out of 24,000 members of the profession in France, some 23,988 do not seem to need any other control than that of their own conscience.

Malaria Therapy.

Professor Claude advocates the creation of centres of malaria therapy for the treatment of general paralysis of the insane. The results are very gratifying, and a special kind of *Plasmodium vivax* has been cultivated by Bouman and Lee for the purpose. It is used against all severe forms of syphilis of the central nervous system, and very likely it is merely by raising the temperature of the body that malaria counteracts the spirochaete. Professor Claude hopes that this new form of therapeutics will be applied in all cases of general paralysis throughout France, and the Academy of Medicine has adopted his views.

Sequels of Vaccination Against Typhoid Fever.

Professor Achard, who has just been elected a member of the Académie des Sciences in succession to the late Professor Widal, has given his experience in the late results of vaccination against typhoid fevers. In his ward there were far more cases of paratyphoid infection than of true typhoid in 1925 and 1926; it was the reverse in 1928. The mortality was 8.5 per cent. in paratyphoid, against 15 per cent. in typhoid fever. The benefit of preventive vaccination was proved by the fact that women patients greatly outnumbered men, the male population having been vaccinated during the war. The proportion was 4 to 1, and the males were under 21, therefore no vaccination immunization seems to last after the age of about 16. Professor Chauffard maintains that everyone should be vaccinated against enteric fever three times: in early childhood, at the age of 10, and at 15. In the recent epidemic in Lyons women were infected in the ratio of 5 to 1 man, and practically none of them had been vaccinated.

Two New Members of the Academy of Medicine.

Professor Gustave Roussy of Geneva, who has claimed his rights of French citizenship, is a descendant of the old Huguenot stock; he has been elected a member of the Academy of Medicine. He succeeded the late Professor Letulle in the chair of anatomo-pathology. He studied first in Geneva, and came to France to work under Dejerine and Pierre Marie. He is well known for his work on experimental medicine, and regards pathology not so much as being a pure morphological science, but rather as a dynamic science, linking morbid anatomy to it. Since the war he has been studying cancer, and has created the Cancer Institute of the Medical Faculty of Paris; he is considered the protagonist in the fight against cancer in France, and his election has met with unanimous approval. Sir StClair Thomson's election as a corresponding member of the Academy of Medicine is the highest honour that can be bestowed in France on a medical man. The election has been most cordially approved by the profession, happy to greet a man who is as popular in France as he is in Great Britain, and who is in every sense of the word quite at home on this side of the Channel. We trust that his perfect knowledge of French may allow him, from the Academy platform, to maintain and develop the links holding together the British and French medical schools. We call our academicians "les immortels"; Sir StClair is highly qualified to add to immortality a quality that it may sometimes seem to have lost—perpetual youth.

G. MONOD.

Scotland.

Scottish Association for Mental Welfare.

THE annual meeting of the Scottish Association for Mental Welfare was held in Edinburgh on May 18th. Sir Henry S. Keith, who presided, mentioned that the association had a membership of 375. Unfortunately a large number of the bodies at present represented would disappear when the Local Government (Scotland) Act came into operation. Professor G. M. Robertson, physician-superintendent, Royal Edinburgh Hospital for Mental Disorders, and professor of psychiatry, gave an address on the supervision of the mentally defective, with special reference to the Jordanburn Nerve Hospital and Psychological Institute. The aims and scope of this new departure received notice in the *British Medical Journal* of March 9th (p. 468). Professor Robertson said that the number of defectives in Scotland was estimated to be about 40,000. The class which gave rise to most anxiety and trouble was that of young adult defectives of the higher grades. In the absence of help and friendly supervision, these were apt to develop into criminals or social failures of one kind or another. Preventive measures must depend on early detection and appropriate training when young, a suitable occupation, and protection from unequal competition when adult life was reached. Steps were now being taken to meet these needs, and in this connexion Professor Robertson mentioned the Gogarburn Institution, of which (as recorded below) the foundation stones were laid by the Duke and Duchess of York on May 22nd. Two recent developments in Edinburgh University were commendable, as they indicated a long overdue realization of the importance of laying stress in medical training on the mental factor in disease. They were the appointment of Dr. Clarkson of Larbert as lecturer on mental deficiency, the first post of the kind in any university in this country, and the compulsory attendance of all medical students at a course of lectures on psychology. The opening of the Jordanburn Hospital by the managers of the Royal Mental Hospital was important in relation to these two academic measures. It was a voluntary hospital for the treatment of a group of disorders of the nervous system not otherwise specially catered for—borderland cases like hysteria and obsessions, mild psychoses like depressive and delusional states, mental subnormalities like high-grade defect, and abnormalities of disposition and personality. It was a teaching hospital, connected with the University and Medical School. A notable feature was the connexion between the hospital and the psychology department of the University under Dr. James Drever. The number of in-patients that could be accommodated was fifty, but its most useful sphere of activity would probably be in the treatment of out-patients.

New Edinburgh Institution for Mental Defectives.

The Duke and Duchess of York laid the foundation stones of the Gogarburn Institution for Mental Defectives, now under construction by the Edinburgh District Board of Control, on May 22nd. The institution, which is situated about three miles west of Edinburgh, is the first mental defective colony in this country to be built under the Mental Deficiency Act, 1913, and as a pioneer institution presents many interesting and novel features, both in design and in equipment. It will eventually accommodate 1,000 persons, drawn from Edinburgh and the south-east of Scotland. The site comprises the estates of Gogarburn and Kellerstain, and extends to 420 acres. The colony has been designed as a small village, with houses or blocks, each to accommodate fifty patients under the supervision of a housekeeper or nurse. The principal entrance leads direct to the administrative and admission block, which will dominate the colony in every direction. Near-by are the hospital and isolation block, staff accommodation for nurses, kitchen, stores, laundry, and power-house. There are also two residential blocks for higher and two for lower grades of patients. On the south side of the Gogar Burn the remainder of the residential blocks will be grouped around a large campus running east and west. The

division between the male and female groups is formed by the school, church, and recreation hall. At either end of the campus will be situated the various occupational buildings, where patients will be trained and employed in various trades and crafts. The southern portion of the estate contains two farms. Already some of the roads and essential administrative portions are nearing completion, and it is anticipated that two homes, each housing fifty patients, will be ready for occupation in August of this year. The whole scheme is expected to take seven years to complete. The existing Gogarburn House was adapted for the temporary housing of patients some years ago, and there have been about sixty patients in residence for some time.

Royal Visits to Edinburgh Institutions.

The time-honoured visits to medical and nursing institutions in the city of the Lord High Commissioner to the General Assembly of the Church of Scotland and his lady have this year had a special significance. It was regrettable that a mild outbreak of infection prevented the first of these, to the Royal Edinburgh Hospital for Sick Children. On the forenoon of May 23rd the Duchess of York visited the headquarters of the Scottish Branch of the Queen's Institute of District Nursing in Castle Terrace. Her Royal Highness, who has recently succeeded Princess Louise, Duchess of Argyll, as president of the Scottish Branch, was welcomed by the Countess of Mar and Kellie, chairman of the council. The latter recalled that their first president had been Lady Rosebery, a fact that came to them just then with a poignant significance as they mourned the passing of Lord Rosebery. During the forty years of the Institute's existence 722 nurses had been trained in that building, and had then found their way as missionaries of health to all parts of Scotland. The Duchess, in reply, expressed the pleasure it gave her to become president of the Institute, and to know that the splendid work of the Queen's Nurses was appreciated in Scotland. Five nurses who had served the Institute for twenty years in different parts of the country were presented with long-service badges. On the afternoon of the same day the Duke and Duchess of York spent a busy hour at the Royal Infirmary, visiting a surgical and a medical ward, inspecting the massage department, and presenting prizes to the nurses. Sheriff Brown, on behalf of the managers, in formally thanking Their Royal Highnesses for their visit, referred to the impending celebration, in the autumn of this year, of the two hundredth birthday of the Royal Infirmary, and of the fiftieth anniversary of their occupation of the present buildings.

Ireland.

Amalgamation of Hospitals in Dublin.

SIR WILLIAM DE COURCY WHEELER has recently suggested in a published statement that the limitations imposed on the hospitals by charters and vested interests could be overcome by a short Act of the Dáil. To set the Dublin hospitals on their feet in a great amalgamation scheme probably £1,000,000 would be required. If the basis for a general agreement could be found—an agreement approved by the Government—there was little doubt that the money would be forthcoming from such a generous mine of wealth as the Rockefeller Trust. Amalgamation of hospitals did not imply of necessity the fusion of all the existing hospitals. Two large centres would be equally effective—one for the north and the other for the south side of the city. Alternatively, the smaller hospitals might amalgamate, and the larger, if they so desired, could continue and extend their admirable work as separate units. Dublin hospitals, Sir William Wheeler added, were pulling their weight in the face of difficulties and contributing their quota to the knowledge of the world.

Mr. William Doolin, at the annual meeting of the Coombe Linen Guild, defended the system of small hospitals in Dublin. He said that if the aim of the teaching authorities was to produce a few outstanding specialists by intensive training, at the expense of the bulk of the students, then he granted amalgamation was the best way to achieve their end. He cited the French and German hospitals, whose educational systems had just such an outcome, to the regret of their own more thoughtful teachers. They in Ireland were a small and poor people. Their unit was the small farmer community on the land. Ought they not to cut their coat according to their cloth? Their medical educational system was by no means perfect; so far from having exhausted their teaching resources, they failed to make full use of what they had at their disposal. Yet each year their small hospitals—by virtue of their intimacy and their number—actually turned out a more than sufficient number of well-trained general practitioners, of a higher average value to their national community than the products of any other training centre of his acquaintance. Their resident student system and their midwifery teaching system were the envy of many educational authorities in England and on the Continent.

Medical Inspection of School Children in Dublin.

Dr. Molly O'Leary, assistant medical officer of health, Dublin, in a recent statement on the medical inspection of school children in the city of Dublin, said that out of 12,000 children inspected during the year 1928, 262 were found to have heart lesions. In 50 per cent. of cases there was a history of previous illness, but the fact that the growing child's heart is easily dilatable was borne in mind, and the parents were warned against allowing them to be unduly fatigued or over-exerted; the high tenement houses and high-storied buildings were not favourable for this type of child. The remaining cases were of organic disease, and though a history of diphtheria or scarlatina was elicited in some cases, the greater number were rheumatic in origin. Rheumatic children generally gave a history of growing pains and repeated sore throats, and were usually nervous, anaemic, and poorly nourished. General attention to hygiene and diet, to the value of milk, the care of teeth, the removal of septic tonsils, and the avoidance of damp localities and clothing were impressed upon their parents. Constant supervision and inspection of children exhibiting rheumatic tendencies were desirable. In the course of the year's inspection fourteen children were found to be suffering from chorea, and their parents were quite unaware that it was a rheumatic manifestation. During the past year 959 children were treated for dental defects at the various hospitals and at the dental clinic, while 330 had their septic tonsils removed. These figures did not include those who went to their own dentists and doctors. The dental clinic of two sessions per week, which was instituted in October last, had now been extended to three sessions. Every effort was made to send children from the ages of 5 to 7 years for conservative treatment in order to avoid wholesale extractions in later years.

The Story of the Rotunda Hospital.

The Rotunda Hospital, Dublin, which is now making an appeal for funds, is the subject of an article by Mr. Frederick Miller, which appeared in the Dublin *Sunday Independent* on May 19th. The Rotunda, Mr. Miller recalls, was founded by Bartholomew Mosse, a native of Maryborough, in the Queen's County, who practised medicine in Dublin in the early part of the eighteenth century. His work among the poorer sections of the population made him acutely aware of the wretched plight of women who had to undergo their confinement without medical aid, and he resolved to do all in his power to establish a hospital in which poor patients could receive free nursing and treatment. After a period devoted to the study of hospital systems in France, Holland, and other European countries, he returned to Dublin in 1745, and having furnished a house in St. George's Lane (now South Great George's Street), he opened it as the first hospital of its kind in the British Isles. To meet the cost of the undertaking Mosse contributed his own money and organized lotteries, plays, concerts, and oratorios. Handel was invited to Dublin, and is said to have conducted there the first performance ever given of his *Messiah*, for the benefit of the hospital. In 1748, finding the accommodation—namely, twenty-four beds—inadequate, Mosse, at a cost of £

£2,000 of his own money, laid out a garden and promenade on a piece of waste ground which he had secured in Great Britain Street, and used the revenue from admission fees paid by the nobility and gentry living in Dublin for the purpose of building the Rotunda Hospital. He started to build with only £500 in hand, but though by the end of 1755 he had collected £11,694, he found that this sum, as well as the whole of his personal fortune, was insufficient for his purposes, and on March 23rd, 1756, in response to his petition, the Irish Parliament allowed him an additional grant of £6,000. On November 11th Parliament gave him yet another £6,000, with £2,000 for himself as a reward for his labours in the cause of humanity. On December 8th, 1757, the building being nearly completed, the upper floor, furnished with fifty beds, was opened by the Duke and Duchess of Bedford. Mosse fell ill in the winter of 1758, and died in the following February. If in 1750 the Rotunda Hospital benefited to the extent of £4,000 by the concerts held in the gardens, Mr. Miller suggests that, by similar means, it should be possible in 1929 to raise part of the funds at present required for the upkeep of this world-famous institution.

England and Wales.

Health Statistics for the First Quarter of 1929.

THE abnormally cold weather experienced during February and March has left its trace in the form of an increased mortality rate, as is shown by the return of the Registrar-General, in which it is stated that during the first quarter of the year the deaths registered in England and Wales numbered 204,293, which is 67,978 in excess of that for the corresponding quarter of 1928. This represented a death rate of 21 per 1,000 of the estimated population, which was 7.1 per 1,000 above that recorded during the first quarter of last year. With the single exception of the March quarter of 1919, when, owing to the influenza epidemic the rate rose to 21.3, the figure for 1929 was the highest recorded in any first quarter of the present century. This high mortality figure is attributable in a large measure to influenza and various respiratory and circulatory diseases favoured by the low temperature. Influenza was stated to be either an immediate or a contributory cause of death in 23,763 cases, or 11.63 per cent. of the total deaths registered. This may be compared with the results of the previous influenza epidemic in the March quarter of 1927, when the figures were 17,931 and 10.62 respectively. The mortality of infants under the age of 1 year was equal to 111 per 1,000 of registered live births. This rate was 14 per 1,000 above the average of the ten preceding first quarters, and is the highest rate recorded in any quarter since the first one in 1919. The natural decrease of population by excess of deaths over births was 44,112; in the corresponding quarter of 1926 there was an increase in this respect of 43,386, in 1927 a decrease of 1,786, and in 1928 an increase of 31,611. The highest death rates from influenza in 107 of the larger towns last quarter were: 4.18 in Norwich; 4.32 in Stoke-on-Trent; 4.39 in Doncaster; 4.41 in Leeds; 4.42 in Worcester; 4.84 in Walsall; and 5.99 in Oldham. During the quarter small-pox was mentioned as a cause of death in eight cases. The Registrar-General's report contains a supplementary table showing the distribution of the cases of small-pox notified during the thirteen weeks ending March 30th.

The Order of St. John and the British Red Cross Society.

The ninth report of the Joint Council of the Order of St. John of Jerusalem and the British Red Cross Society—the first to deal with a calendar year—covers the period from January 1st to December 31st, 1928. The Council records that the total number of cases helped by the auxiliary hospitals for officers' department is now 17,923; of these, 355 officers, including 125 new cases, received help during the twelve months under review. Most of the cases at present are ex-officers suffering from tuberculosis. Owing to the lapse of time since the war, tuberculous ex-officers find it increasingly difficult to satisfy the Ministry of Pensions that their disability is due to war service, and the department has supplied a real need in coming to their assistance where immediate aid has been essential pending the investigation of their cases by the authorities concerned. The department has in many instances met the full sanatorium fees, though, whenever it was necessary, the Officers' Association has generally helped to the extent of one-half. The officers' hospital at Brighton continues to do good work, 86 ex-officers (40 coming through the Ministry of Pensions) having received in-patient treatment during the year. In May, 1928, the Joint Council considered and approved a proposal that its hospital and medical services department should become a central bureau of hospital information, under the auspices of the British Hospitals Association of the Joint Council. The formation of such a bureau had been advocated for some time, and the Joint Council feels assured that, now the bureau is established upon a sound basis, its value to the voluntary hospitals will regularly increase. During the period under review 755 provincial and voluntary hospital reports have been received and analysed, and the ninth annual report of the voluntary hospitals in Great Britain (excluding London) for 1927 has been compiled and issued. The bureau aims further at collecting and summarizing the data concerning all matters of administrative interest to those engaged in hospital management, to undertake inquiries with the object of obtaining facts from those responsible for guiding hospital policy, to establish a library where literature dealing with matters of hospital administration, construction, and equipment can be consulted, and to act as a clearing house of information in order that all the experience acquired might be made generally available. The Christmas gifts provided for ex-service pensioner patients in hospital on Christmas Day, 1928, numbered 5,774, at a total cost of £1,441, of which £932 4s. 6d. was administered direct by the Joint Council, and the remainder through the Ministry of Pensions. Approximately 16,000 ex-service pensioner patients in hospital have been provided with motor drives by the Drives and Entertainments Fund. The Emergency Help Committee set up by the Joint Council in December, 1920, continues to administer a scheme for providing relief to thousands of sick and disabled ex-service men and their dependants. During 1928, 26,913 new cases were assisted or otherwise dealt with, the present average monthly expenditure on grants being about £6,000. During the year the committee received £8,053 in voluntary refund of advances made under the scheme. In November, 1924, the committee undertook the administration of a grant for the purpose of providing motor attachments to the invalid chairs of disabled service pensioners, and up to the present 464 men have been loaned motors, the number in actual use on the last day of 1928 being 354. During the twelve months the Games and Comforts Fund made 298 grants of additional comforts and articles of recreation to applicants from Ministry of Pensions hospitals and other institutions treating ex-service pensioner patients. The Home Ambulance Service is extending the range of its activities, and an account of its work during the year was published in our issue of May 18th (p. 924). The work done in the stores department has been steadily maintained, air-beds and water-beds, first-aid cabinets, sterilizers, furniture, and many other necessities having been supplied to hospitals, nursing institutions, child welfare centres, and medical supply depots. In July last the Joint Council Committee of Management decided to dissolve the Tuberculosis Subcommittee on the grounds that the individual needs of officers and men were now met by other committees, and following upon this dissolution the administration and management of Scio House were taken over by the House Committee, thus ensuring no break in the continuity of the work. Grants for ward industries work were given to nine hospitals, six of which were Ministry of Pensions institutions, and during armistice week articles made by patients doing ward industries in hospitals in London and the provinces were displayed as part of the exhibition and sale of ex-service men's work held at the Imperial Institute. The Finance Committee reports that the expenditure for the year has exceeded income by £814, which compares

with a deficit of £1,025 for the previous nine months. The council hopes that, with an improvement in industrial conditions, its income may grow, and that the present annual depreciation in its resources may come to an end.

Proposed Thank-offering Fund in Jersey for the King's Recovery.

A representative meeting of the inhabitants of Jersey was held on May 18th to inaugurate a local thank-offering fund for the recovery of the King, who is also Duke of Jersey. The Lieutenant Bailiff, who presided, expressed the opinion that the money collected in Jersey should be used for the relief of the local sick, and recalled that when in 1897 a collection was made for the erection of the Victoria Cottage Homes the amount obtained was doubled by the States. He suggested that on the present occasion it would be a good plan to purchase radium. Dr. C. H. B. Avarne commented on the value of radium in the treatment of cancer, which he thought was more prevalent in Jersey than in communities of the same size on the mainland. In his opinion an adequate local supply of radium would be of very great value and could be effectively used by the island surgeons. Dr. A. E. Hind doubted whether radium had yet passed beyond the experimental stage, and mentioned that the results following its use in England had not been invariably encouraging. In any case he held that its administration should be localized in a large institution, and be entrusted to experts. [A letter from Dr. Hind on this subject is printed at page 1020.] Dr. P. J. Marett thought that the money, when obtained, would be better expended on a clinic for the treatment of the prevalent lung infection in Jersey. It was eventually agreed that the money collected in the island as a thanksgiving for the King's recovery to health should be retained in Jersey and form the nucleus of a fund for combating disease. The hope was expressed that the States would double the amount raised. A general committee was appointed, and, though it was decided that the collecting should not start until July, it is announced in the *Jersey Evening Post* that an offer of 100 guineas has already been received.

London School of Hygiene and Tropical Medicine.

The pamphlet recently issued by the London School of Hygiene and Tropical Medicine, and discussed in a leading article this week (p. 1007), confines itself to a consideration of the school from the standpoint of a school of hygiene, there being a separate prospectus and calendar to deal with its duties as a school of tropical medicine. The school is intended to serve both as a teaching and research institution, and to train post-graduate students, more especially those proceeding to degrees and diplomas in public health, in all branches of preventive medicine. It consists of the following divisions: (1) public health, which includes the section of physiology as applied to hygiene; (2) epidemiology and vital statistics; (3) bacteriology and immunology; (4) biochemistry, including a department of chemistry as applied to hygiene; (5) medical zoology, including departments of protozoology, helminthology, and entomology; (6) tropical medicine and tropical hygiene. All these divisions are fully equipped to provide post-graduate instruction to medical men and women who desire to enter the public health services or to be trained in methods of research, or to undertake actual investigations within the fields covered by the divisions. The staff of the school being in contact with other official research organizations, students will have exceptional opportunities of acquiring experience of the way in which large-scale investigations on public health problems are planned and conducted. The course of study for a diploma in public health extends over a period of twelve calendar months, divided into three terms of twelve weeks each. The directors of the school, while hoping that students will as far as possible devote the whole of their time to the work, have decided to meet the needs of students not in a position to attend both in the morning and in the afternoon by arranging the course so that those prepared to give five afternoons weekly from 2 to 6 will be able to comply with all the conditions laid down by the General Medical Council. Students who can attend three afternoons a week may still comply with these conditions by spreading the course of study over two years, but only at the expense of rendering less effective the efforts that have been made to co-ordinate the teaching of the various divisions of the school. Whole-time students will be given extra-tutorial and practical work in the mornings, and will be encouraged to make arrangements with medical officers of health to obtain additional practical public health experience. Included in the syllabus are some forty special lectures by recognized experts on various public health problems, and a similar number of visits to selected places of outstanding public health interest. Students will do practical work under a medical officer of health in two selected areas, and attend institutions of the Metropolitan Asylums Board for three months' instruction (at least thirty attendances of two hours each) in infectious disease and hospital management. The course in applied physiology will comprise twelve lectures and demonstrations, and in sanitary engineering twenty lectures and practical classes. Those responsible for drawing up the curriculum have aimed at presenting the teaching in a logical sequence and at co-ordinating the work of the different departments, and to accord with this aim a uniform date of entry is regarded as essential, students being expected to start work at the beginning of the autumn term. The composition fee for the year's course has been fixed at fifty guineas, payable at the time of enrolment. This fee includes payments in respect of work in a public health department and of instruction in infectious diseases and hospital management.

Gas and the Public Health.

London members of the Society of Medical Officers of Health were entertained at luncheon by the Gas Light and Coke Company on May 24th, and afterwards visited the company's research laboratories and training centres. Sir David Milne-Watson, chairman of the company, who presided, after welcoming the guests as advisers of local authorities on the ever-widening range of subjects connected with public health, reminded them that the headquarters of the company at Horseferry Road, Westminster, where the luncheon took place, was a *locus classicus* of the gas industry, being the original home of gas in the metropolis. Gas was made on that very spot in 1812, when Pall Mall was lighted by gas, an illuminant to which it still remained faithful. Dr. J. B. Howell, chairman of the metropolitan branch of the society, in acknowledging the hospitality, said that there could be no doubt that the diminution in the intensity and frequency of London fogs was due largely to the more common use of gas for heating and cooking. It was always the domestic chimney, not the factory chimney, which was the principal agent in atmospheric contamination. Another point mentioned by Dr. Howell was the value of the residual products, especially coke, with which one medical colleague of his was heating his house entirely, thereby eliminating ash and smoke, lessening labour, and securing a higher and more uniform heating effect than with raw coal. Dr. Charles Porter, medical officer of health for Marylebone, spoke of the great help which medical officers received from those engaged in gas manufacture and distribution. Mr. G. S. Elliston, secretary of the society, added a few words on the contribution of the gas industry to smoke abatement. The company were then taken to Watson House, Nine Elms, where they witnessed the testing of appliances in special laboratories, and the methods of research, always going forward, on the fundamental problems of the combustion of gas and coke, including the character of the fuel and of the products of combustion and their removal, the transfer of heat from the products and its conservation, and the question of ventilation. Some work now proceeding relates to the corrosion of pipes by water, and the protection of mains by a suitable coating when they are laid in soils excessively acid or alkaline. The visitors also inspected the welfare department, which includes provision for training in first-aid and the prevention of accidents. The Gas Light and Coke Company serves 265 square miles of the metropolitan area and consumes 23 million tons of coal a year.

Correspondence.

THE INTRODUCTION OF PERCUSSION INTO ENGLAND.

SIR,—Absence abroad has prevented my seeing, till yesterday, Mr. J. F. Fulton's letter in the *Journal* for April 13th (p. 708).

Who first practised percussion in this country I do not know, but it was an Englishman who first noticed Auenbrugger's discovery, which he announced in 1761. Ronald S. Crane[1] has recently brought to light the very interesting fact that Auenbrugger's book was introduced into England by Oliver Goldsmith, who wrote a review of it in the year of its publication—namely, 1761. Being himself a physician this he was qualified to do. Goldsmith gives an admirable abstract of the book, and concludes: "Such are the outlines of this new discovery; whether it may be of use to society or not there is no necessity for me to pretend to determine; only this may be observed: that the lungs are often, in the most healthy state, found to adhere to the pleura, and in such a case I fancy the sound would, in that part, deceive the practitioner; however, I shall not pretend to set up my conjecture against his experience." The first French notice of it was the publication, in 1770, of a translation by Rozière de la Chassagne.—I am, etc.,

London, May 22nd. W. HALE-WHITE.

THE VOLUNTARY HOSPITALS AND THE BRITISH HOSPITALS ASSOCIATION.

SIR,—I think it would be satisfactory if we could have some information as to the position of the voluntary hospitals and the British Hospitals Association in the matter of the organizations that the latter undertook to set up in the English counties for establishing the fullest co-operation between the voluntary and the statutory hospitals. It would be an advantage to know how far these organizations have been carried through, and under whose control they are to be. Are they to be managed by the British Hospitals Association? And to whom are they to report? So far, this has not been made clear.

As regards Scotland, the organization that has been created in the West of Scotland hospital area by the Scottish Regional Committee—now to be called "The Scottish Branch of the British Hospitals Association"—is in a most unsatisfactory position, as there has been no announcement of the names of the committee. The secretary of the Scottish Liaison Committee, when applied to some weeks ago for a list of the members of this West of Scotland Regional Committee, could not furnish this, as it had apparently not been supplied to him. Matters have been further complicated by this West of Scotland Regional Committee assuming to itself the name of "The Scottish Regional Committee of Voluntary Hospitals in the West of Scotland." There are no grounds to justify this being done. This regional committee has not been elected by the voluntary hospitals, nor has any mandate been given by the voluntary hospitals of the West of Scotland area to the British Hospitals Association to form such a committee. The committee, when first formed by the Scottish Regional Committee of the British Hospitals Association, was a Hospitals Association committee, and was to consider how best to establish the fullest co-operation between the voluntary and the new statutory hospitals, and to lay its views before the Scottish Health Committee; its opinions were not those of the voluntary hospitals in the area, but of the members of the committee. To call itself, as it has done, 'The Regional Committee of the Voluntary Hospitals of the West of Scotland Area" is to assume a title to which it has no claim, and to take up a position that it has no authority to occupy.

The point that ought not, at present, to be lost sight of is that the changes in our English and Scottish hospitals services introduced by the new Local Government Reform Act chiefly affect the interests of our teaching hospitals with medical schools. Consequently, the relations between them and the statutory hospitals should be discussed and considered by representatives of the physicians and surgeons who form the staffs of these teaching hospitals. Co-operation between the two groups of hospitals involves delicate negotiations, which do not lie within the sphere of work of the British Hospitals Association, which has not the necessary knowledge in the matter, as it is largely composed of lay members, and as it was established to consider questions of hospital management and to furnish provision for instruction in administrative hospital work. It is very important that the teaching hospitals connected with the medical schools should recognize this fact, both in England and in Scotland, and that the medical and surgical staffs are the proper bodies to be consulted in settling this co-operation. One need hardly point out that such co-operation would materially assist the medical schools, as the voluntary hospitals would be able to draw on an enlarged field of clinical material, and with an interchange of staffs should find their usefulness strongly reinforced.—I am, etc.,

Glasgow, May 27th. GEORGE THOS. BEATSON.

IMMUNITY TO TUBERCULOSIS.

SIR,—I feel I must comment on a statement in Dr. Nathan Raw's paper on "The production of immunity to tuberculosis in man and animals" (May 25th, p. 950), although it is with considerable diffidence that I venture to criticize any remarks made by one with such wide experience as Dr. Raw. He says that "patients suffering from pulmonary tuberculosis rarely develop bone, joint, or gland lesions, and vice versa; in fact, that the human subject is protected by one infection against the other." Although this may be true in certain parts of the country, it is certainly not the case among adults in a large industrial city such as Sheffield. I have always a considerable number of patients under my care with tuberculous bones, joints, and glands who have also lung lesions, as proved by clinical, radiographic, and bacteriological examination.

Perhaps the reasons for the difference in our two views may be understood by examining another of the statements made by Dr. Nathan Raw, that "human bacilli cause primary pulmonary tuberculosis, while the bovine type cause enlarged glands, mesenteric disease, bone and joint lesions, etc." It is true that in 1912 Fraser found that 65.6 per cent. of bone and joint cases in Edinburgh were bovine in origin, and that in 1916 Griffith determined that of 25 cases in Scotland 32 per cent. were bovine. But in the same year Griffith found that of 103 patients living in England and Wales only 15.5 per cent. had bovine infection.

In 1924 Drs. Edington and Guest, working with pus from 33 Sheffield children, found that 84 per cent. were due to the human type of organism. Indeed, in Sheffield it could hardly be otherwise, for the opportunities for infection with the human bacillus are so numerous, whereas the chance of infection with the bovine type is insignificant, since so little milk is drunk here. It has been estimated that the amount of milk entering the city allows only about a quarter of a pint per head daily, comparatively little of which will, of course, be available for the poorer inhabitants. Also, the milk supply of Sheffield is singularly free from tuberculosis infection compared with that of many other big towns.

Therefore it may be definitely stated that in Sheffield: (1) many adults with primary pulmonary lesion due to the human type of bacillus do develop secondary bone affections; and (2) many cases of bone tuberculosis in children are due to the human type of organism.—I am, etc.,

C. LEE PATTISON,

May 27th. Surgical Tuberculosis Officer to the City of Sheffield.

GROWTH RECOVERY AFTER INHIBITION BY LEAD.

SIR,—I am not quite clear what was the object of Dr. Hammett's communication in the *British Medical Journal* of May 18th (p. 886). Was his chief concern to dissociate his findings with any application of them to the clinical treatment of cancer with lead? If so, he will be hard put to it to do so, for the mere fact that lead inhibits mitosis, as described by Dr. Hammett, is of great

importance in this connexion. In any case, there is nothing new in many of his findings or in his qualification that recovery from the inhibitory effect of lead applied for a short time to vegetable growth takes place. This has already been stated by us (cf. W. J. Dilling, *Ann. App. Biol.*, 1926, xiii, 160); but Dr. Hammett does not appear to have read this and other of our papers, published long before he commenced his own investigations.

Perhaps Dr. Hammett will extend his observations to hyacinths and use stronger solutions for a much longer time—say, three to six months; he will then probably be able to find lead in the bulbs, as Patterson did, and to observe in those immersed in lead-free water some months later that the fresh root-growth is also stunted (vide W. Blair Bell, *Lancet*, 1924, i, 267, and W. Blair Bell and J. Patterson, *Ann. App. Biol.*, 1926, xiii, 157).

It is very wise of Dr. Hammett to infer that animal tissues may be even more permanently affected than vegetable. There is a considerable literature on the subject; but space forbids detailed reference to it.

We have also repeatedly mentioned in our clinical papers (cf. W. Blair Bell, *British Medical Journal*, 1929, i, 431) that arrest of growth in a neoplasm may be followed by regenesis after the cessation of lead administration, and we have in consequence recommended a more protracted period of treatment in certain cases. The "whole story," as propounded by Dr. Hammett, is, indeed, a very small fraction of the complete account.—I am, etc.,

Liverpool, May 22nd. W. BLAIR BELL.

DISTRIBUTION OF RADIUM.

SIR,—I would be very grateful for an authoritative opinion on a point of policy. Jersey, with its population of about 50,000, wishes to raise a thanksgiving fund for the King's recovery, the money to be spent in Jersey, the purpose proposed being relief of suffering. A public meeting was held on May 18th, and one member of our profession ardently advocated that such money as was collected should be used for the purchase of radium for local use. I opposed this as being possibly premature. First, on the ground that, the supply of radium being limited, such as is available could be used better elsewhere—that is, in large institutions and in the hands of skilled men. Secondly, that the use of radium was not yet quite out of the experimental stage, and that at some future time our present estimates of its value may have to be reconsidered. I thought that some scheme of preventive medicine would be more advisable.

It is quite possible that my views were wrong; but I did not feel justified in supporting the radium scheme in the circumstances. Of course, we would like to have unlimited radium to experiment with; but I do not think we are justified in asking a confiding public to subscribe. Some of my colleagues are attacking me in the public press for what they consider antiquated views. I do not mind that so long as my opinion is right. I think that in inexperienced hands more harm than good might result from the use of radium, as the temptation to use it in hopeless cases would be great.

Would it not be cheaper for a small community such as ours to hire radium as required? Sarcoma cases are not of everyday occurrence, nor a cancer case in a condition to be cured by radium; London is not very far off, and the suitable cases could go there.—I am, etc.,

Jersey, May 22nd. ALFRED E. HIND, F.R.C.S.Ed.

STELLWAG'S SIGN AND THE CERVICAL SYMPATHETIC.

SIR,—Dr. W. T. Collier, in your issue of May 25th (p. 973), refers to my advocacy of Stellwag's sign as a valuable diagnostic aid in early Graves's disease (*British Medical Journal*, May 11th, p. 848), and asks for some further information.

Stellwag's sign is the phenomenon of widening of the palpebral fissure due primarily to a condition of increased tonus which occurs in a thin sheet of unstriped muscle (Müller's palpebral muscle), which is anatomically associated with the levator palpebrae superioris muscle of the upper eyelid. The levator palpebrae superioris derives its motor supply from the oculo-motor, whereas Muller's muscle derives its motor supply from the cervical sympathetic. The point which I wished to make in my article is confirmed by this anatomical fact—namely, that in early Graves's disease sympatheticotonicity is a symptom which can be detected at any early stage of Graves's disease, and that improvement results from administering sodium veronal, a drug which I have shown elsewhere[1] overcomes the sympatheticotonicity which is frequently associated with the menopause.

It would seem that the eye is peculiarly affected in all conditions of sympatheticotonicity, since I have shown[2] that some women and most animals at the menopause have pupils which dilate when adrenaline is instilled into the conjunctival sac, a phenomenon which does not occur in normal individuals, but may occur in Graves's disease. Finally, in order to complete my thesis I would say that I have found Stellwag's sign present in three women at the menopause unassociated with Graves's disease.

Some success has attended operations on the cervical sympathetic for Graves's disease, notably those recorded by Mr. Cunliffe Shaw in this *Journal* (March 16th, p. 495). In Case ii of his series he refers to the general improvement which occurred after cervical sympathectomy, and noted the remarkable improvement which occurred in the condition of spastic retraction of the upper eyelids, which was a marked feature of the case prior to operation. It would seem that I have obtained similar results by administering a drug which has a powerful sedative action on the sympathetic nervous system generally.—I am, etc.,

London, W.1, May 24th. JOHN H. HANNAN.

Obituary.

HUGH LATHROP MURRAY, F.R.C.S.Ed., F.R.C.P.Ed.,

Honorary Medical Officer in Charge, Physiotherapy Department, Melbourne Hospital.

THE news of Dr. Hugh Lathrop Murray's death, on March 17th, in his sixtieth year, at his home near Melbourne, will be received with deep regret by his friends in this country and elsewhere. He was born at Ararat, Victoria, the second son of Kynaston Lathrop Murray, a former commissioner of the Victorian railways, and was educated at Queen's College, St. Kilda, Melbourne, and at Melbourne University. In his school and college days he was a very fine all-round athlete. While an undergraduate he won championships at swimming and putting the weight, and played lacrosse for Victoria against South Australia, New South Wales, and a visiting team from Canada. At 21 he threw the lacrosse ball 163 yards 2 feet, which remained the world's record until it was beaten by the present holder, his brother Cecil. Hugh Murray studied the later subjects of the medical curriculum at Edinburgh, where he obtained the triple qualification in 1892. He was then appointed resident physician to the late Dr. Andrew Smart at the Royal Edinburgh Infirmary, and in 1893 acted as medical superintendent of the Edinburgh Provident Dispensary. He obtained the diplomas of F.R.C.S.Ed. and M.R.C.P.Ed. in 1894, and was elected a Fellow of the Royal College of Physicians of Edinburgh in 1904.

On returning to Australia in 1895 he settled in East Malvern, a residential suburb of Melbourne, where he built up an extensive and successful general practice, and at the same time began to specialize in the then greatly developing fields of medical electricity and x-ray work. He was examining medical officer to the Victorian railways from 1898 to 1903, and in the latter year published an ophthalmological paper in the *Intercolonial Medical Journal*, embodying his experience and suggesting improvements in the tests for acuity of vision and hearing among railway employees. In 1901 he received the appointment of honorary medical electrician and lecturer on medical electricity at the Melbourne Hospital. At that time the department was housed in a single room, and run by him

[1] Hannan: *Practitioner*, October, 1927.
[2] *British Medical Journal*, November 24th, 1928, p. 931. Ibid., June 2nd, 1927, p. 14. *Endocrinology*, 12, 1928, pp. 59-64.

and an assistant attending on two afternoons weekly. Under Hugh Murray's regime, and due almost entirely to his efforts, it gradually developed into the present magnificent department of physiotherapy, occupying one complete wing of the hospital, having a staff of twelve assistants, and dealing with an average of 400 patients weekly. About 1909 the *x*-ray department was placed under a separate head, Murray having contracted an exposure dermatitis, which, although a constant source of annoyance, fortunately remained stationary, and his appointment on the staff was specially altered in name to that of honorary medical officer in charge of the department, whose growth under his supervision will be a lasting memorial of his fine record of service for the hospital and the community of Melbourne. Hugh Murray's professional and social activities, however, sought wider fields. He was the founder of the Australian Massage Association, and under his leadership the Victorian Branch succeeded, after repeated attempts, in inducing the State Parliament to pass a Massage Registration Act, regulating the practice of physiotherapy, and requiring the registration of all those engaged therein, including masseurs, physical culturists, medical electricians, and ultra-violet ray administrators. He was chairman of the Massage Registration Board from the passing of this Act until the end of 1928, in which year he published in the *Medical Journal of Australia* a notable paper based on his experience and life-work, and entitled "A plea for physiotherapy." During the war he served in 1916 as regimental medical officer with Australian battalions in Egypt, and in France with the 2nd Australian Division, and in 1917 in England, where, as captain A.A.M.C., he organized and was in charge of the department of medical electricity at No. 3 Australian Auxiliary Hospital. On his return to Melbourne he was promoted to major, and finally to lieutenant-colonel, A.A.M.C., medical officer in charge of the physiotherapy department of No. 11 General Hospital, Melbourne, where he carried on his army work till 1921, and successfully treated many cases requiring muscle re-education. During his years of war service his practice had suffered, and his efforts to re-establish it on his return undoubtedly had a good deal to do with the sudden break-up of his health in 1923. Hugh Murray always looked back on his student and hospital days in Edinburgh as among the happiest of his life, and no notice of his career would be complete without a picture of him as he then was in the prime of early manhood. He was a man of splendid physique, standing well over 6 ft., with the muscularity and the strength and also the activity and grace of movement of the all-round athlete, with handsome aquiline features and dark curly hair and moustache, and with the happy smiling eyes and cheerful voice that always bespoke the warmth and sincerity of the camaraderie and humanity of his nature. Among his many and quite exceptional endowments of body and mind, which he utilized well and faithfully, he will always be specially remembered by his old friends for the delightful experience and treats which he gave to them by his glorious singing. He was a really gifted singer, and was much in request in the Edinburgh days at public concerts and private social functions.

His eldest son is Dr. Hugh M. L. Murray, now working at University College, London; and his second son is Flying Officer Lee Murray, R.A.F., who with his wife recently flew in his Moth aeroplane from Peshawar to Camooweall, Queensland, en route to Melbourne.

C. C. E.

The death occurred, at the age of 60 years, of Dr. GEORGE BELL ANDERSON on May 15th, at his residence at Canonbie, Dumfriesshire. Dr. Anderson received his medical education at Edinburgh University, where he graduated M.B., C.M. in 1893. He succeeded to an extensive general practice at Canonbie on the death of his father (Dr. James Rae Anderson) in 1896, and, like his father, successfully carried on the practice single-handed until his death. He literally "died in harness," having visited patients to within a few hours of his decease, although he had been very ill since the previous Sunday. Dr. Anderson was a member of the British Medical Association, medical officer to the Canonbie Colliery, and medical officer and public vaccinator for Canonbie Parish. He was of a cheery disposition, endowed with indomitable pluck, and inured to the hardships inseparable from the life of a country practitioner. His high sense of honour earned the respect of his colleagues, and his innate kindness of heart endeared him to all. Much sympathy is felt for his widow and only child, a son who is studying medicine at Edinburgh University.

Dr. WILLIAM HANDCOCK, who died on May 17th, at the age of 63, was one of the most widely and deeply esteemed medical practitioners in Bradford, where he had been in practice for thirty-five years, building up a constantly increasing connexion which necessitated his taking first one, and later a second, partner. He received his medical education at Leeds, obtaining the diploma L.S.A. in 1892, and the L.R.C.P.I. in 1893. He took little part in public work, but was one of the general practitioners chosen to serve on the medical committee of the Bradford Municipal Hospital when it was established in 1920, and as long ago as 1904 he was president of the Bradford Medico-Chirurgical Society, being elected to this office at a younger age than any other man who has received the honour. He was unmarried. Mr. James Phillips, senior surgeon to the Bradford Royal Infirmary, writes: Handcock was one of the best type of general practitioner, a friend to all his patients—rich and poor alike—as well as a physician. He had an old-world courtesy of manners, which was appreciated even by the most up-to-date and "off-hand" of his younger patients, and he possessed the knowledge and self-confidence in his powers of diagnosis which inspired confidence in his patients. Throughout his busy life he was constantly keen on acquiring knowledge of advances in treatment, and he appeared to have an almost uncanny power of "spotting" the useful newer remedies and eschewing those which, however highly vaunted, a short experience later showed to be of little value. He could very rarely be persuaded to contribute to the programmes of the local medical society, but that he held very definite opinions and had the ability and courage to express them cogently and clearly was shown when he delivered his presidential address on the demerits of alcohol as a therapeutic agent.

Dr. GEORGE SKELTON STEPHENSON, who died on May 18th in his eighty-first year, studied under Lister at Edinburgh in the seventies; his neatly written note-books of those lectures are still carefully preserved. Many years subsequently he produced a delightful little book, *Reminiscences of a Student's Life*, in which he has many tales to tell of the great men of those days, and of his fellow students; among those who graduated M.B. with him in 1875 were Sir W. Watson Cheyne, C. S. Ryan, and Professor Rutherford Morison. From Edinburgh he went to Vienna for a further year's study of pathology and physiology under Brücke, but he also attended the skin clinics of Hebra and the surgical demonstrations of the celebrated Billroth, who was accustomed to sit in state while a student, summoned from the crowd, performed the day's operation under his instruction. There he developed a love for the German language and literature which persisted to his latest years. He returned to settle in his native place, Grimsby, at a time when there were few, if any, other doctors there, and he has related that he had to deal with no fewer than eight confinements in his first forty-eight hours of practice. He graduated M.D. in 1889. A colleague writes: Dr. Stephenson belonged to one of the oldest Grimsby families, and at one time took a great part in the public life of the town. He was a governor of the Old Clee Grammar School, and a magistrate for twenty-six years. As medical officer to the Post Office and a medical referee for North Lincolnshire he rendered long and excellent service, and for twenty-five years was senior surgeon to the Grimsby Hospital, retiring under the age limit. Although in failing health for some time, he continued his duties as public vaccinator to within three weeks of his death, when he was still

officially surgeon to the Admiralty. His interests were unusually various; he had a collection of stamps, was something of a connoisseur of old prints and furniture, was expert in the compounding of sauces and in other gastronomic lore, and his store of varied experiences and keen observations made him the best of company. I can speak very gratefully of the steady encouragement and constant generous kindness that in so many ways he invariably showed me, both as a student and as a beginner in general practice; a humanity which makes him well worthy to be ranked as a typical "doctor of the old school."

The following well-known foreign medical men have recently died: Dr. GEORGES GÉRARD, professor of ophthalmology at Lille, Dr. TRUC, honorary professor of clinical ophthalmology at Montpellier, aged 72; Dr. ZINOVY PETROVITCH SOLOVIOV, president of the Russian Red Cross, professor of social hygiene at Moscow and chief of the sanitary service of the Red Army; Dr. BAEZ, formerly president of the Republic of San Domingo and rector of the University; Dr. CHARLES TALAMON, a Paris physician who described the pneumococcus in 1883, and one of the earliest writers on appendicitis, aged 78; Professor PAUL JUNGMANN, director of the first medical clinic of the Charité Hospital, Berlin, and one of the founders of the *Klinische Wochenschrift*, aged 42; and Dr. José SEGOVIA of Caballero, professor of surgical pathology at Valencia, aged 31.

The Services.

DIRECTOR-GENERAL A.M.S.

MAJOR-GENERAL HAROLD B. FAWCUS, C.B., C.M.G., D.S.O., at present Deputy Director-General Army Medical Services, at the War Office, has been selected for the appointment of Director-General, in succession to Lieut.-General Sir Matthew Fell, K.C.B., C.M.G., who is retiring at his own wish in September next.

Colonel W. R. BLACKWELL, C.M.G., late R.A.M.C., has been selected to succeed Major-General Fawcus as Deputy Director-General A.M.S.

Major-General H. B. Fawcus was born in 1876, and has been D.D.G.A.M.S. since 1926. He graduated M.B., B.S.Durh. in 1899, entered the R.A.M.C. in the following year, and took the D.P.H.Camb. in 1905. He was assistant professor at the Royal Army Medical College, 1912–14, and instructor to the School of Army Sanitation, 1914. He served in the South African campaign, 1900–2, receiving the Queen's medal and four clasps and the King's medal and two clasps, and also in the European war, 1914–18, when he was mentioned six times in dispatches and awarded the C.M.G., D.S.O., and the Croix de Guerre.

Colonel W. R. Blackwell entered the R.A.M.C. in 1899, and served during the South African campaign, 1899–1902, when he was mentioned in dispatches, and in the European war, 1914–18 (dispatches thrice). He also served in the Afghanistan campaign, 1919–20. He was D.A.D.G.M.S. at General Headquarters, France, in 1918, and A.D.M.S., Army Headquarters, India, in 1919–23.

OSBORNE CONVALESCENT HOME FOR OFFICERS.

THE KING has approved the appointment of the following to the consulting staff of King Edward VII Convalescent Home for Officers at Osborne, Isle of Wight: Sir Cuthbert Wallace, K.C.M.G., C.B., F.R.C.S., Professor George E. Gask, C.M.G., D.S.O., F.R.C.S., Professor C. C. Choyce, M.D., F.R.C.S., E. Rock Carling, M.B., B.S., F.R.C.S., Sir William H. Willcox, K.C.I.E., C.B., C.M.G., F.R.C.P., C. H. Miller, C.B.E., M.D., F.R.C.P., H. Morley Fletcher, M.D., F.R.C.P., Sir James Purves-Stewart, K.C.M.G., C.B., M.D., F.R.C.P.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

At a congregation held on May 24th the following medical degrees were conferred:

M.D.—V. D. Wigglesworth, L. B. Winter.

M.B., B.Chir.—J. R. H. Towers, H. W. Nicholson.

THE BRITISH MEDICAL JOURNAL

Medical News.

THE Prince of Wales, as President of King Edward's Hospital Fund for London, has appointed Mr. Edward Robert Peacock as Treasurer of the Fund and Chairman of the Finance Committee, in succession to the late Lord Revelstoke.

THE Duke of Connaught will present the prizes to successful students at St. Thomas's Hospital Medical School on Tuesday, June 11th, at 3 p.m., in the Governors' Hall.

THE Section of Surgery of the Royal Society of Medicine holding its next meeting at Sheffield on Wednesday, June 12t from 2 to 6 p.m.

THE Lord Mayor of London, as President of the Metropolitan Hospital Sunday Fund, announces that it has been arranged that the collections on Hospital Sunday, June 2nd, will form part of the Thank-offering Fund for the King's recovery. The whole of the amount paid into the Hospital Sunday Fund collection will be distributed to the hospitals and medical charities of London by the committee of that Fund in the usual way.

SIR Arthur Stanley and Sir Harold Pink, the president and chairman, respectively, of the British Hospitals Association, have addressed a letter to the lord mayors and mayors in the provinces with reference to the collections to be made in places of worship on June 16th, as a thanksgiving for the King's recovery. They suggest that appeals should be opened in the local press in this connexion by the mayors for the benefit of local hospitals, it being made clear that those who respond are in fact taking part in the national thanksgiving. They add that if these subscription lists are closed on Saturday, June 15th, this will allow the total amount collected this means and through the church offertories to be ascertained and announced early in the following week. Donors who wish to help provincial hospitals generally without especially marking their donations for any particular institution are invited to send them to the president of the British Hospitals Association, at 19, Berkeley Street, W.1. Such moneys will be administered in accordance with any wishes expressed by the donors.

THE Fellowship of Medicine announces that a course for M.R.C.P. candidates is now in progress at the Medical Society of London, 11, Chandos Street, Cavendish Square; lectures are delivered twice weekly on Tuesdays and Fridays at 8.30 p.m. Professor Hugh MacLean will lecture on June 4th on nephritis, with special reference to cardiovascular involvement, and on June 7th on recent views on diabetes and insulin. On Thursday, June 6th, at 3.30 p.m., Dr. Willmott Evans will give a clinical demonstration at the Hospital for Skin Diseases, Blackfriars Road, and on Saturday, June 8th, Mr. F. D. Saner will give a clinical demonstration on fractures, at 10.30 a.m., at the Royal Northern Hospital, Holloway Road. There is no fee for attendance at either of the demonstrations. From June 3rd to 22nd, at the Royal Westminster Ophthalmic Hospital, there will be a course consisting of clinical instruction and operations from 2.30 p.m. onwards, and at 5 p.m. on Mondays Thursdays, and Fridays special classes will be given. From June 10th to 22nd there will be a special course in gynæcology at the Chelsea Hospital for Women consisting of instruction by operations and lectures, including pathological demonstrations. During the same period a course in diseases of the chest will be held at the City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, comprising special demonstrations in the wards and out-patient departments, and formal lectures by the staff. The entire practice of the hospital is open to those taking the course. A week's whole-day course in proctology will be available at St. Mark's Hospital from June 24th to 29th. An intensive course in medicine, surgery, and the specialties will be held at the Prince of Wales's General Hospital, from June 24th to July 6th, in conjunction with the North Middlesex Hospital and other associated hospitals. The Children's Clinic, in association with other hospitals, such as the Royal Waterloo Hospital and the National Heart Hospital, will conduct a two weeks' course in children's diseases from June 24th to July 7th. All information regarding the foregoing courses and particulars of the general course can be obtained from the secretary of the Fellowship, 1, Wimpole Street, W.1.

LORD MESTON, Chancellor of the University of Aberdeen, presided over the Congress of the Royal Institute of Public Health, at Zürich, from May 15th to 20th. At the inaugural session he thanked the president of the Swiss Republic for the cordial welcome extended to the congress, and commented on the contributions to modern civilization made in Zürich in the past as well as in the present. The president, in his reply, emphasized the value of applying the model

discoveries of science in connexion with hygiene to communal life in a State. The delegates, in addition to sessional discussions, visited the local centres of interest, particular attention being paid to the notable efforts of the local authorities to ensure the preservation of the public health.

AT the thirtieth annual meeting of the Lebanon Hospital for Mental Diseases, which was held on May 21st, at the Friends House, London, Dr. Fortescue Fox, who was in the chair, mentioned his recent visit to Syria, and emphasized the importance and magnitude of the task of caring for the insane in that country. He described the work undertaken by the Lebanon Hospital (to which reference was made in the *Journal* of August 20th, 1927, at page 331) and announced that the hospital had now become to a great extent self-supporting, but it still looked to the Central Committee in London and affiliated committees for money for such capital expenses as new buildings and structural improvements. Dr. E. W. G. Masterman, chairman of the London Committee, stated that authority had been telegraphed to proceed with the provision of additional private rooms for acute female cases at a cost of £300, but two new houses were needed, one for men and one for women. A proposal was under consideration for erecting a New Zealand memorial house with fifty beds. Other speakers supported the claims of this hospital, of which the London office is at 139, Marylebone Road, N.W.1.

WE are informed by Professor O. S. Gibbs, M.B., of Dalhousie University, Halifax, Nova Scotia, that Messrs. Parke, Davis and Co. have given a donation of £300 to the department of pharmacology to enable an assistant to investigate the action of the separated pituitary principles on the renal function of the fowl, following up some work already published. This gift, purely for research, is the first of its kind to the medical school in Nova Scotia. Messrs. Parke, Davis and Co. have previously presented drugs and specimens for teaching.

AT the last meeting of the House Committee of the Royal East Sussex Hospital at Hastings it was reported by the secretary that during April accidents to motor drivers and their passengers cost the institution £102 2s. 8d.; the amount received from the injured in acknowledgement of the help given was only £12 1s. 6d.

THE Minister of Health has issued a circular (No. 989) to food and drug authorities in England and Wales calling their attention to the Artificial Cream Act, 1929, which comes into operation on June 1st. This Act provides that cream substitutes hitherto known as reconstituted cream, and usually prepared by emulsifying butter, dried skimmed milk, and water, shall not be sold under a designation including the word "cream" unless this word is immediately preceded by the word "artificial." Receptacles must be similarly labelled, and premises manufacturing or selling artificial cream must be registered with the local authority.

AN account of sclerosis of the retinal vessels was contributed by Dr. N. Pines to the March, April, and May issues of the *British Journal of Ophthalmology*. This has been reprinted as a pamphlet by the publishers of that periodical, Messrs. George Pulman and Sons, Ltd., 24, Thayer Street, W.1.

BURROUGHS WELLCOME and Co. (Australia) Ltd. have removed their offices and warehouses from Kent Street, Sydney, to Victoria Street, Waterloo, Sydney, where commodious premises have been built near the company's works and laboratories.

THE Home Office has recently issued a second edition of its memorandum on First Aid and Ambulance for Factories and Workshops (Welfare Pamphlet No. 4, H.M. Stationery Office, price 4d.) for the guidance of overseers of factories and workshops in establishing a satisfactory first-aid and ambulance service.

A REPORT on the school of midwifery of Hong-Kong University was published by Professor R. E. Tottenham in the *Caduceus* for November, 1928, and a reprint has now reached us. It is illustrated by numerous photographs of the large Tsan Yuk Maternity Hospital, for the founding of which the late Dr. Alice Hickling was largely responsible. Professor Tottenham gives details of the satisfactory progress of obstetrical and gynaecological treatment and training in the island, and supplies a statistical account of the maternity and gynaecological departments of this hospital and the special wards in the Government Civil Hospital.

THE Water Pollution Research Board of the Department of Scientific and Industrial Research has issued a further summary of current literature relating to water supplies, sewage, trade waste waters, river pollution, and miscellaneous subjects. The booklet has been placed in the Library of the British Medical Association, where it may be consulted.

A NEW Scandinavian journal with the title *Nordisk Medisinsk Tidsskrift* has been started by a group of well-known medical men in Denmark, Finland, Norway, and Sweden. It is published weekly in Stockholm (Eriksbergsgatan 1 A, Stockholm) and is printed in one or other of the Scandinavian languages. In the second number, a biographical sketch of Richard Sievers is followed by three signed original articles, and by abstracts from other Scandinavian journals. There are already many medical journals of high standing in the Scandinavian countries, but their output of scientific work is so great that the need was felt for a journal which would unite the Scandinavian research workers on common ground.

THE following appointments have recently been made in foreign faculties of medicine: Professor G. C. Riquier has been transferred from Sassari to the chair of neuropathology and psychiatry at Bari, Professor J. Staeheliu has succeeded Professor H. Rudin in the chair of psychiatry at Basle, Professor K. Reuter of Hamburg has been appointed professor of legal medicine at Breslau, Professor L. Preti has been transferred from Catania to the chair of medical pathology at Parma, and Professor C. Lotti has been transferred from Cagliari to the chair of medical pathology at Pisa.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9861, 9862, 9863,* and *9864* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:
EDITOR of the *British Medical Journal, Aitiology Westcent, London.*
FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*
MEDICAL SECRETARY, *Mediocra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

INTRACTABLE DIARRHOEA IN A DIABETIC PATIENT.

"R. M." asks for suggestions for the treatment of persistent and uncontrollable diarrhoea—occurring at intervals during sleep—in a man aged about 60, who is a diabetic, and is taking insulin. None of the usual remedies appear to have any lasting effect. X-ray examinations have proved negative. The stools show only lack of digestion of fat and meat fibres. Pancreatic extract tablets, emetine-bismuth iodide, small doses of castor oil, bismuth, etc., have all failed to control this very distressing disability. The condition has lasted for eight months; the loss of flesh and weakness are getting more marked. The insulin has not been taken very regularly.

DURATION OF LIVER TREATMENT OF PERNICIOUS ANAEMIA.

"W. L." asks for advice regarding treatment of pernicious anaemia. Is it necessary to continue the administration of liver extract when the blood picture has become nearly normal, and, if so, how often per week?

MALARIA IN SOUTHERN RHODESIA.

DR. F. T. ANDERSON (Cheltenham) writes: Can any reader tell me if malaria and blackwater fever are prevalent throughout Southern Rhodesia? In the article on education and the prevention of malaria (May 18th, p. 919) it is stated "blackwater fever which has been such a bane to white colonists in Southern Rhodesia."

SEQUELS OF INJECTIONS OF VARICOSE VEINS.

DR. A. HINES (Manchester) writes: The statement of "M.B., C.M." on May 25th (p. 979) is quite correct. Many of my patients have had injection operations on both legs. The "tired" and "heavy" feeling, local oedema, and eczematous skin persist, and may even get worse. I find an Unna's paste legging of great benefit, but it has to be worn always when getting about.

PAINFUL HEEL.

"A. G. N." writes: "Giza" (May 11th, p. 893) should exclude an earlier wearing away of the boot heel at a particular part from method of walking. I found this to be the case with me. The *left* postero-lateral part of my boot heel wears away first, and if this is not soon repaired I get a most painful foot. I have had several cases of *painful heel due to this simple cause, and in each*, as soon as the boot was repaired early, the pain disappeared. I *never have it now*, owing to the early attention, but I am warned as soon as the boot wears down. An easy method of relieving pain of the heel when in bed is *simply to let it lie* outside on the edge of the mattress.

INCOME TAX.

Depreciation of Motor Car.

"D. D. M." bought a £330 car in February, 1926; what can be claim for depreciation allowance?

*** Depreciation should be claimed at the time the return is *made for assessment*, or, *at any rate*, within the time limited by *statute for the lodging of appeals—that is, within twenty-one days from the issue of the notice of assessment. We gather* that in the present case the inspector of taxes is willing to make an allowance for the year 1928-29, but not for earlier years. On that basis the allowances, etc., work out as follows:

1926-27—£330 at 15 per cent.—that is, £50 not allowed.
1927-28—£330 − £50 = £280 at 15 per cent.—that is, £42 not allowed.
1928-29—£280 − £42 = £238 at 15 per cent.—that is, £36 allowed.
1929-30—£238 − £36 = £202 at 15 per cent.—that is, £30 to be allowed.

It will be seen that "D. D. M." has definitely lost, so far as the depreciation allowance is concerned, the first two years' amounts —that is, £50 + £42 = £92. But this can, no doubt, be picked up when his car is replaced, by the operation of the obsolescence allowance; for instance, suppose he sells the car in 1929 for £120 and buys another to replace it, then he will be able to claim the obsolescence allowance in computing his taxable *profits* for *assessment* for 1930-31, the allowance being £330 − (£36 + £30 depreciation allowances *granted*) − £120 (received for the car), net allowance, £144. If he had received the depreciation allowances for the two early years the obsolescence allowance would have been £330 − (£50 + £42 + £36 + £30) − £120—that is, £52.

Obsolescence Allowance.

"M. S." bought a motor-cycle combination in 1922 for £150, and by 1929-30 the depreciation allowances had reduced that amount to £62. He then sold the combination for £22 and bought a car for £135. He has claimed a *deduction* of £62 − £22 = £40 "for replacement" (strictly it should be for obsolescence), but the claim is refused on the ground that "no allowance can be made for the *loss on replacement* . . . as this is a capital loss."

*** "M. S." *should* write pointing out that the claim should *be regarded as one* for "obsolescence allowance." We are quite clear that that claim should be admitted, and if it is still refused we suggest that our correspondent should put the facts before the authorities at Somerset House and ask for their ruling on the matter.

"T. C. L." bought a car in 1925 for £435, and for the three years ending April 5th, 1929, received depreciation allowances amounting in the aggregate to £213. He sold the car on March 28th, 1929, for £90, and bought a new car for £315. What should he claim?

*** (1) Obsolescence allowance £435 − £213 − £50 = £172, and (2) depreciation on the new car £315 at 20 per cent.—that is, £63. We have assumed that "T. C. L." makes his accounts up to March 31st or April 5th; if the date chosen is earlier than March 28th—for example, December 31st—the allowances stated above will affect his liability for 1930-31 and not 1929-30, and the depreciation allowance for 1929-30 will be £222 at 20 per cent. = £44, and the obsolescence allowance, affecting the 1930-31 liability, will be £435 − £257 − £50 = £128.

Purchase of Share in Partnership.

"T. D. M." has bought a one-fifth share in a partnership as from April, 1928. His cash income for his first year was about £700, but his share of the partnership tax has been calculated on the basis of approximately £900, the other £200 representing the *value of his share of* outstanding debts at the end of the first year.

*** The basis on which the £900 is calculated is correct. Income tax is payable on the amount of the earnings *of the year*, whether received in cash or still due.

LETTERS, NOTES, ETC.

ANTIBACTERIAL POTENCY OF THE BLOOD IN PREGNANCY.

DR. A. W. CRAWFORD (Bolton) writes: I was much interested by the communication on the bactericidal property of the blood *during pregnancy made by* Drs. Miller and Whittaker, and *reported* in your issue of May 18th (p. 904). The following quotations are taken from a pamphlet published years ago by me in relation to serums which had been used by Cabanis and Foulquier: "Those *patients suffering from* cancer and other various diseases were calling upon the reparative powers of the system which *most likely* were making a supreme effort to withstand the invasion of foreign and poisonous materials thrown into the blood, and that the blood of pregnant women is highly charged with formative material which is embryonic in character." "Those serums have in some way stirred up the formative material of *cancerous subjects*." I have said before that it is this formative material of the blood which is defective in pernicious anaemia, and is analogous to the *defective* epithelial *substance in cancer*. It is the corpuscles of the blood which are attacked by poisonous invasion. Their defence and increase are carried on by the formative material—namely, *platelets*, *plasma*, or polymorphs—and they are of epithelial origin. The above bears out my theory of cancer. What researchers have now to look for is the influence which *retards* or prevents the growth of this formative material at its very source. There is a point I should like to draw your attention to. After delivery the *antibacterial and nutritive* power disappears in ten days. Thereafter there is a temporary increase of a substance which is purely *antibacterial*, as the nutritive element is not required for the sustenance of the child. In the last paragraph of the paper the authors admit there is some, as yet, [illegible] which stimulates activity of *growth and* [illegible] *nracter*. Dr. Leitch has said he intended [illegible] to activity of growth, as the germ theory had no foundation.

CHRONIC ACNE.

DR. STEPHEN M. LAWRENCE (Trinidad) reports the following two cases of acne of long duration. The first was a young man who suffered severely from pustular acne; he was treated with *x rays*, without success, small abscesses *forming from time to time*. About a year ago a large abscess over the jaw was opened, after which *acute inflammation spread to the neck*, with a considerable cellulitis. Free incision and the removal of sloughing tissue brought about rapid improvement, which included the disappearance of the acne spots, the skin having since remained quite smooth. The second patient was a young woman, aged 21, who had had acne indurata *since the age of* 18. The use of a liquid soap gave only temporary relief. Under vaccine treatment there has been great improvement. The initial dose of combined acne vaccine *injected was 2,000 million—ten times* the normal dose. *No reaction followed*, and within a week an injection of half this dose was given. As there was only slight fever and malaise the doses were repeated, and, finally, the maximum dose of 2,000 million was *given twice a week*. The pimples now only return occasionally and soon disappear. Dr. Lawrence considers that vaccine therapy might be more effective if larger doses than usual were employed, especially when the disease is of long standing.

A WARNING.

DR. DONALD F. JOHNSTONE (Chatham) *writes to warn readers* against a man describing himself as a Canadian doctor who consults medical practitioners in England, presumably in order to obtain morphine by false pretences. "His procedure is to state that he has a severe renal colic and haematuria, and then ask for morphine to relieve the pain. He gives a distant address, and refuses offers of treatment at home, in case it may alarm his wife. He talks so convincingly that I was completely deceived, and his simulation of a renal colic is excellent. He is shabbily dressed, but talks with an educated Canadian accent, and he is quite au fait with all matters medical. There are two scars on [illegible] from some gall-bladder operation and [illegible] out that immediately after obtaining a dose of morphine [illegible] atropine from me he consulted two other doctors near by and obtained further supplies from them. In all three cases the story was the same, and we were all promised a box of Canadian apples for our kindness. Needless to say, these have not arrived."

THE USE OF THE TONSILS.

DR. J. MCNAMARA (Kensington) writes: Dr. Gardner (May 25th, p. 980) says that in Abyssinia it is *the custom* to remove the tonsils of all children, without evil results. It is highly improbable that the native of Abyssinia, *by a horse-hair noose*, can remove the whole or even half of a tonsil. Even if the whole of the tonsil were removed without evil results in the children of a *people living* in the healthy, sun-swept mountain atmosphere of Abyssinia, it does not follow that similar results would attend a similar operation in the children of people living in the polluted atmosphere *of our cities*. As an argument against the theory *that the* tonsils are useless after 5 years of age, I may mention that in animals of mucky habits, like the pig, the defensive ring of tonsillar tissue around *the throat* is highly developed.

THE Editor of the *Cambridge University Medical Society Magazine* asks *us to* state that communications should be addressed to him *care* of Messrs. Heffer and Sons, Ltd., 4, Petty Cury, Cambridge.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges and of vacant resident and other appointments at hospitals, will be found *at pages* 42, 43, 44, 46, 47, 50, 51, 52, and 53 of our advertisement columns, and advertisements as to partnerships *and locumtenencies* at pages 48 and 49.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 211.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

512. The Clinical Syndrome of Coronary Obstruction.

P. GOVAERTS (*Le Scalpel*, March 9th, 1929, p. 253) asserts that coronary obstruction should be recognized as a clinical entity, though in many textbooks its description is lost among details regarding angina pectoris. Both ventricles receive branches from both coronary arteries, but the apex of the left ventricle derives its blood supply exclusively from the descending branch of the left coronary artery—a vessel which is, of all those supplying the heart, most nearly an "end artery." The nodes of Keith and Tawara have a variable blood supply, sometimes from one and sometimes from the other of the main coronary trunks; hence the inconstancy of rhythmic disturbance following obstruction. The extent of the anastomoses between terminal branches of the main coronary trunks is variable; it is sometimes so great that occlusion of a main trunk may give rise only to trifling clinical disturbance. The anastomosis is never so complete, however, as to prevent altogether some degree of necrosis in the area supplied by the occluded vessel, though the area of necrosis may be much reduced. The cause of coronary obstruction is most commonly arterio-sclerosis; sometimes a syphilitic aortitis may cause a gradual occlusion of the coronaries at their origin, but obstruction by embolic fragments from endocardial vegetations is more rare. Obliteration of minor vessels may give rise to small degrees of cardiac insufficiency with occasional attacks of pain; in the case of larger vessels there is usually sudden violent pain referred chiefly to the left precordium and the epigastric region, and death may be instantaneous or may follow an aggravation of pain. If recovery ensues after obstruction of a major vessel it is usually slow, and a more or less serious cardiac insufficiency persists. Govaerts lays stress on the diagnostic importance of the sudden onset of pain in major coronary obstruction and also its character, particularly its frequent reference to the epigastrium, but he notes that sometimes the pain may not be very severe, though in these cases the occurrence of a sudden dyspnoea, followed by signs of cardiac insufficiency, should indicate the diagnosis. The results of obstruction depend on the extent of the fibrosis which follows the inevitable necrosis of a greater or less area of the cardiac muscle. Occlusion of the descending branch of the left coronary artery—the "site of election" in coronary obstruction—may result (if instant death from ventricular fibrillation does not ensue) in the formation of a cardiac aneurysm from dilatation of the large area of fibrosis in the heart wall. Among the signs and symptoms of cardiac insufficiency lowering of blood pressure is the most constant; dyspnoea is common, and there may be typical pulmonary œdema or renal and hepatic stasis. The electro-cardiograph may indicate modifications, even in the absence of rhythmic disturbance, and without gross irregularities the pulse may show a remarkable instability of rate. The signs of infarction are a moderate leucocytosis of 12,000 to 15,000, and the occurrence of pericardial friction. Infarction more commonly reaches the endocardium than the pericardium; in the former case emboli may be formed, lodging in the pulmonary circulation if from the right side of the heart, or in the brain or other regions of the systemic circulation if from the left side. Differential diagnosis may have to be made from acute abdominal conditions and angina pectoris; in anginal attacks the blood pressure is frequently high and may become higher during the attack. Other simulating conditions are pulmonary embolism secondary to venous thrombosis, and rupture of the aorta; this rare condition seldom occurs without preceding signs of aneurysm. The prognosis is not invariably bad, but the general resistance to disease is always lowered, and cardiac arrhythmia, if it happens to result, frequently persists. The most important part of treatment is rest. For the immediate cardiac collapse camphor and strychnine are of service, and for the later persistent insufficiency digitalis and strophanthus are indicated.

513 A Para-dysentery Epidemic.

S. A. LARSEN (*Ugeskrift for Laeger*, April 18th, 1929, p. 309) gives an account of the first milk-borne para-dysentery epidemic described in Denmark. It occurred in a small town of between four and five thousand inhabitants, and altogether 116 cases were examined. The onset was sudden, 59 persons suffering from sanguineous and mucous diarrhoea between June 10th and June 15th, 1927. After June 24th the number of new cases fell to an average of one or two a day, until the epidemic ceased on July 13th. The milk supply of the town came from three dairies and a certain number of private farms. It was ascertained that 103 of the 116 patients had consumed milk from the same dairy, which supplied barely 30 per cent. of the town's total milk supply. Of the 59 patients whose symptoms began on or before June 15th, as many as 58 had consumed milk from the dairy in question. Of the 40 patients who fell ill between June 16th and June 25th, 36 had consumed milk from this dairy. Of the 16 who fell ill between June 26th and July 13th, 8 had consumed milk from the same dairy. It will thus be seen that in the initial stage of this epidemic, while it was still a "vehicle epidemic," the infection could be traced to one and the same source in almost every case, whereas the longer the epidemic lasted the more did it assume the character of a "contact epidemic," with several new sources of infection. It transpired that two girls, living on one of the six farms supplying the dairy, had suffered from violent blood-stained and mucous diarrhoea, one of them falling ill on June 11th, the other on June 17th. The latter was found still to harbour Sonne's para-dysentery bacillus in the faeces when they were examined about the end of June. The same bacillus was isolated at the Serum Institute in Copenhagen from all the six samples of faeces of the first acute cases examined bacteriologically on June 22nd.

514. The Cardio-vascular System in Typhus Fever.

P. DECOURT (*Paris Méd.*, April 13th, 1929, p. 357) states that the heart is one of the organs most frequently affected in typhus, though often only in a mild degree. During the first two days the pulse is strong, regular, and about 90, but on the third or fourth day it tends to become soft and not infrequently dicrotic. There is often a dissociation between the pulse and the temperature at this stage, the pulse being 90 and the temperature 104°. By the sixth or seventh day the pulse is between 110 and 130 in every case, and subsequently follows the temperature. Towards the twelfth day, shortly before the temperature falls, the pulse becomes softer and there are frequently extra-systoles and inequality of the radial pulses. As the temperature drops the symptoms become more marked and may persist for two or three days after the temperature has become normal. Moreover, there is often at this stage a dangerous cardiac instability, the pulse, which has become normal, suddenly showing a fresh acceleration as the result of a slight effort. The blood pressure is lowered in typhus as in all grave infections. At the onset the depression is slight, but subsequently tends to increase, especially towards the twelfth or fourteenth day, when there is a rapid fall of blood pressure, chiefly affecting the maximum tension. The blood pressure generally rises again as the temperature falls, but often remains low for a very long time after the temperature has dropped. The cardiac complications of typhus chiefly resemble those of typhoid fever, and consist in extra-systoles, tachycardia, and collapse, giving rise to sudden death.

515. Syphilitic Pancreatitis.

M. CAMPAGNA (*Journ. Amer. Med. Assoc.*, March 16th, 1929, p. 894) remarks that syphilis is occasionally masked by manifestations of some other disease symptom-complex; he reports a case of syphilitic pancreatitis which exactly simulated diabetes. A man, aged 28, who had previously been healthy and gave no evidence of venereal infection, received a severe injury to the right foot. On examination a moderate degree of arterio-sclerosis and complete sloughing of the right great and second toes were noted. The pain was intense. The blood sugar reading was 175 mg. per 100 c.cm. of blood, and the Wassermann reaction was negative. With diabetic diet and insulin the blood sugar dropped to 80 mg., but no improvement occurred in the foot, which was accordingly amputated. The stump did not heal satisfactorily, and the blood sugar rose to 150 mg. Rigid antisyphilitic treatment with neoarsphenamine was then instituted with dramatic results. The unhealthy unhealed stump began to granulate rapidly, and before the third weekly injection the old indolent sore had completely closed. For sixteen months there has been no rise of the blood sugar above normal; the weight has increased, and the patient has been able to resume work without diet restriction and without insulin. The Wassermann reaction remained negative throughout. Campagna emphasizes the fact that there were no physical signs of syphilis, and that before the onset of the gangrene the patient considered himself healthy. Apparently the pancreas was the only organ involved.

516. **Hepatitis in Influenza.**

T. VIEGNER and O. WELLNER (*Med. Welt*, May 4th, 1929, p. 647) record a case of influenza complicated by mild diffuse hepatitis in a man aged 40. The symptoms were rise of temperature, painful enlargement of the liver, subicteric discoloration of the skin and sclerotics, with large quantities of laevorotatory sugar and acetone in the urine. The patient recovered. The authors remark that no previous cases of this complication have been recorded.

517. **Syphilis as a Cause of Accidents.**

O. D. MEYER (*Rev. Sud-Amer. de Endocrin.*, March 15th, 1929, p. 186) maintains that when a person is suffering from syphilis, congenital or acquired, his fitness in a mental, moral, and physical respect is impaired, and he is more susceptible to accidents than normal persons. In his own experience he has found that syphilitic persons have shown a greater percentage of accidents and accidental injuries than the non-syphilitic. Unlike other patients the syphilitic are usually ambulatory, and ordinarily assume the responsibilities of life, with the result that owing to general forgetfulness and lack of alertness and intelligent attention to details they are the constant victims and perpetrators of accidents.

518. **Massive Pulmonary Atelectasis.**

H. K. MOHLER (*Amer. Journ. Med. Sci.*, April, 1929, p. 507) reports two cases of pulmonary atelectasis; one of these occurred during pneumonia and the other was associated with cancer of the stomach. He thinks that pulmonary atelectasis occurs more frequently in association with non-surgical and non-traumatic cases than is generally recognized, and he considers it a definite clinical entity which can be readily diagnosed by the physical signs and clinical course. Displacement of the heart and mediastinum towards the affected side is usually the [illegible] in making the diagnosis, but when the [illegible] the lobules of the lung it may be necessary to verify the clinical findings by x-ray examinations. Mohler believes that the prognosis is generally good; he attributes any unfavourable results to the condition with which the collapse is associated rather than to the collapse itself; he adds, however, that the prognosis is less favourable if the collapse is bilateral and persistent. He favours the mechanical obstruction theory as regards its etiology.

519. **Urethritis not Due to Gonorrhoea.**

ACCORDING to J. WENDLBERGER (*Wien. klin. Woch.*, March 21st, 1929, p. 358) non-gonorrhoeal urethritis is not very rare. He has recently seen three cases in young men who denied any previous venereal infection. Bacteriological examination of smears and cultures showed the presence of staphylococci and streptococci, pneumococci, and *B. coli*, as well as other bacteria which occurred occasionally. Less uncommon were pseudo-diphtheria bacilli, accompanied by a greyish-white discharge. In the first case diphtheria bacilli were associated with staphylococci and pseudo-diphtheria bacilli. No gonococci could be found on repeated examination of smears and cultures. In every case the urethritis was very intractable, and each patient exhibited similar symptoms and bacteriological findings. The author considers that the discovery of true diphtheria bacilli in the male urethra is deserving of attention, and the possibility of this infection should not be overlooked. He refers to the analogous cases of diphtherial conjunctivitis and of diphtherial vulvo-vaginitis in little girls.

520. **Multiple Sclerosis.**

THOUGH multiple sclerosis does not occur with sufficient frequency in families to justify calling it a familial disease, many cases have been noted in different members of the same family, and G. W. ROBINSON, sen. and jun. (*Journ. Amer. Med. Assoc.*, March 16th, 1929, p. 892), report eight cases of this disease in three generations of one family. In addition to the patient himself, a brother, three sisters, and three children of the brother have had multiple sclerosis, while the father and three aunts apparently suffered from the same disease. In these cases the disease usually developed about the age of 30; no trace of syphilis was found, and the spinal fluid and blood were normal. The incidence (2 to 3 per cent.) of multiple sclerosis is not as high as that of other organic nervous diseases. It usually begins between the ages of 25 and 35, and is probably due to some infection resulting in an inflammation of the nervous system. The duration varies from six to twenty-five years, and usually from eight to ten years is the limit of life after the disease can be diagnosed definitely by the symptoms. The treatment is unsatisfactory. The arsenicals are helpful, and very striking improvement has followed antityphoid inoculation. Good results also have been obtained from spinal drainage and the injection of arsphenaminized blood serum intraspinally—a treatment similar to the Swift-Ellis method of treating cerebro-spinal syphilis.

Surgery.

521. **Dilatation of Oesophagus for Cardiospasm.**

E. S. JUDD, P. P. VINSON, and D. G. GREENLEE (*Surg., Gynecol. and Obstet.*, April 1929, p. 494) report two recent cases, a man aged 60 and a woman aged 52, in which dilatation of the oesophagus for cardiospasm was performed from below through a gastrostomy opening. Treatment from above with the hydrostatic dilator, guided over a previously swallowed silk thread, 20 to 24 feet water pressure being used, gave good results in approximately 700 cases at the Mayo Clinic. The method was classed as effectual in 75 per cent. of the cases; recurrence was expected within a year in the remaining 25 per cent., necessitating further dilatation. In the two cases recorded, after several unsuccessful attempts with the hydrostatic dilator from above, the cardia was dilated from below by passing first one and then two fingers into it through an opening on the anterior wall of the stomach, a guiding thread having been previously swallowed. The opening in the stomach was finally closed with chromic catgut and interrupted silk sutures. In the case of the man there was a mild recurrence of symptoms after nine months, but it was then perfectly easy to pass the hydrostatic dilator from above and to stretch the cardia; this afforded complete relief. In the case of the woman, three weeks after operation, x rays showed diminution of the previous oesophageal dilatation and tortuosity and a good-sized opening into the stomach; in three months she was eating all types of food without difficulty. In these cases failure to dilate from above was due to marked angulation of the lower oesophagus, but it is added that the majority of such cases generally yield to treatment with the hydrostatic dilator without resort being necessary to dilatation from below. It was found that the silk thread was as valuable a guide to manual dilatation from below as it was to dilatation from above, and that, though seldom necessary, manual dilatation from below was successful when needed.

522. **Pulmonary Infarction and Embolism.**

C. E. FARR and ROSE SPIEGEL (*Ann. of Surg.*, April, 1929, p. 481) define pulmonary embolism as the metastasis of suspended abnormal elements in the blood, through the right heart, to the lesser circulation, with the resultant effects due to impaction in a pulmonary artery. It may occur in typhoid fever, chronic cardiac valvular disease, lobar pneumonia, tuberculosis, leukaemia; it may also be post-operative. The etiology of thrombosis is summarized as changes in the blood plasma and formed elements, changes in the blood stream, and changes in the vessel wall. Coagulation thrombi depend on the release of fibrin by the interaction of fibrinogen, prothrombin, and calcium salts in the plasma, with thrombokinase from injured leucocytes, blood platelets, or tissue cells; trauma predisposes to thrombosis by the release of thrombokinase from the injured tissue cells. Stagnation thrombi are attributed to local stasis above venous valves, in varices and aneurysms, and in the cardiac chambers, and resemble post-mortem clots. A thrombus is most dangerous when it juts into a larger lumen at the point of junction of a tributary. The proximal part of the femoral vein and the pelvic plexus are the favourite sites, and in abdominal surgery thrombosis originates most often in the left femoral vein. The onset of symptoms is accompanied by a sharp rise in temperature without proportionate changes in pulse and respiration. In pulmonary infarction the early condition is one of hyperaemia followed by local consolidation, and sometimes, by pleural involvement before the terminal cicatrization and formation of the wedge-shaped area. The prognosis is more favourable when phlebitis accompanies the pulmonary symptoms due to the anatomy of the thrombosed vein. Sometimes peripheral phlebitis apparently follows a pulmonary infarction and may be due to the same cause. The symptoms of pulmonary infarction are pleural pain, discomfort in breathing, cough, frothy sputum with bright or clotted blood, sharp rise in temperature, friction rub, small area of slight consolidation, and slightly diminished resonance. The condition can occur at any age, and out of 61 cases recorded 33 were fatal. It was found to be nearly twice as frequent in males as in females, and observations showed that pulmonary embolism predominated in the months of unstable weather.

523. **Appendix Operation Statistics.**

J. JESSEN (*Ugeskrift for Laeger*, April 25th, 1929, p. 329) has been prompted, by the recent agitation in Denmark in favour of the conservative treatment of appendicitis, to publish the records of a large provincial hospital for the 11-year period 1917–27, with a view to confounding the advocacy of conservative treatment and justifying operative treatment. Of the 910 cases of appendicitis admitted in this period, 751 were operated on, 513 *à chaud* and 238 *à froid*. Of the 49 deaths, as many as 47 occurred among the patients operated on *à chaud*; the remaining 2 deaths (both from embolism) belonged to the *à froid* operations. Among the *à chaud* cases there were 177 which were operated on within twenty-four hours of the onset of symptoms, and the mortality was only 1.1 per cent. (2 deaths). It rose to 9.9 per cent. when the interval between the first symptom and the operation was between one and two days. It rose to 17.4 per cent. when this interval was between two and three days, and to 27.2 per cent. when it was three to four days. Among 170 out of 177 cases operated on *à chaud* within the first twenty-four hours of the onset of symptoms, there were as many as 36 in which the appendix was already gangrenous, and 29 (17 per cent.) in which perforation and peritonitis were already demonstrable. By the time the symptoms had lasted three days before an operation *à chaud*, as many as 15 out of 29 patients in this category were found already to be suffering from perforation peritonitis. Of the 513 patients operated on *à chaud*, there were 464 suited for the following analysis: 212 cases of simple appendicitis with a mortality of 2.3 per cent.; 106 cases of gangrenous appendicitis with a mortality of 6.5 per cent.; and 146 cases of perforation appendicitis with a mortality of 23.9 per cent. Of the 47 deaths among the *à chaud* operations, there were only five cases in which simple appendicitis was found; in 7 cases it was gangrenous, and in 35 there was perforation with peritonitis at the time of the operation.

524. **Tuberculosis of the Mesenteric Glands.**

DELIVET (*Bull. et Mém. Soc. Chir. de Paris*, March, 1929, p. 187) discusses a case reported by Dervaux of primary tuberculosis of the mesenteric glands in a girl, aged 18, the symptoms of which led to a diagnosis of appendicitis or tuberculous infection arising in the genital organs. The patient complained of discomfort and pain in the right iliac fossa, with fatigue, loss of appetite and weight, and very marked constipation. She had ceased to menstruate for about three months, but had a purulent white discharge. Examination showed abdominal distension with tenderness over the appendix, and a hard round mass in the region of the right ovary. The temperature was 101.4° and the pulse 100. A right lateral laparotomy disclosed a healthy appendix, but numerous enlarged glands were found in the meso-appendix, round the caecum, and the terminal portion of the ileum. Since these were, in most cases, adherent to vessels, and the glands were so numerous, it was considered dangerous to remove them. Appendicectomy appeared too limited an operation to be of any use, and a radical operation was impossible, so intervention was confined to a simple exploratory laparotomy with exposure of the parts to the air for several minutes. The patient made a good recovery, with the complete disappearance of functional disorders and a rapid gain in weight.

525. **Treatment of Varicose Veins by Injection.**

ELIZA A. MELKON (*New England Journ. Med.*, April 4th, 1929, p. 690) describes the method she uses when treating varicose veins by injection. Four solutions have been employed: (1) sodium salicylate 20 to 40 per cent.; (2) metaphen 1 in 500; (3) sodium chloride 18 to 25 per cent.; and (4) quinine hydrochloride and urethane. When the skin is healthy she prefers the first of these, but when the veins are surrounded by unhealthy skin quinine and urethane is said to give more satisfactory results, and this solution is effective also in cases of haemorrhoids. The patient is kept recumbent when the veins are large, but when they are small the injection is given in the sitting posture. Thin-walled sacs should be avoided, a quick puncture be made, and the fluid injected slowly. Treatment is generally repeated two or three times a week. There are rarely any marked after-results, though occasionally a mild cellulitis occurs due to leakage of the fluid into the surrounding tissues; this clears up in about a week. This type of treatment is said to be contraindicated where there is extensive oedema; when the patient is cold and in poor health; in cases of cardio-renal disease; or where there has been recent phlebitis. The patient is able to continue at his daily work. The author believes that this method will supersede surgical methods on account of its safety, ease of administration, relative inexpensiveness, and satisfactory results.

526. **Malignant Lymphoma.**

M. GOLDENBURG (*Amer. Journ. Ophthalmol.*, February, 1929, p. 116) describes a case of this condition. A woman, aged 56, had noticed for the previous five months a thickening of the left lower eyelid. On examination the left lower lid bulged forward to some extent, but there was no redness or oedema. The lower punctum was not in apposition with the eyeball. On retraction of the lower lid two rolls of greyish-pink tissue were to be seen extending across the whole length of the lower fornix. This mass on palpation was found to be fairly hard, circumscribed, and extending back into the orbit. The overlying conjunctiva was freely movable. A Wassermann test was negative. A small section of the growth was removed for microscopical examination, and showed a dense lymphocytic accumulation beneath the epithelium. Under local anaesthesia the neoplasm was removed. The pathologist reported that there was an extensive accumulation of large lymphocytic cells, with tendency to infiltrate the surrounding tissue. The growth was quite vascular, but the stroma was delicate, and a diagnosis of malignant lymphoma seemed to be warranted. The wound healed satisfactorily, and subsequently four applications of radium were made. There has been no recurrence since the operation two and a half years ago.

Therapeutics.

527. **The Treatment of Diabetes.**

ACCORDING to L. I. BRAUN (*Journ. Med. Assoc. of South Africa*, March 23rd, 1929, p. 151) diabetic cases fall into four groups according to age: childhood, in which it is always grave; from 15 to 40; from 40 to 55; and the aged. The third group of cases (40 to 55) is the one most commonly encountered and most easily controlled. Insulin is not often necessary in these patients unless acute signs arise, and the treatment of a typical patient, aged 42, is outlined; he should be carefully examined for oral sepsis, pulmonary tuberculosis, cataract or retinitis, and for arterial degeneration in the legs. The first step, then, is to free the patient from excess of sugar; this can be done in one of three ways: by starvation, which Braun never employs; by the early use of insulin, which he follows only in very severe cases; or by a basal diet, which is one which will supply all the necessary bodily energy and heat without loss of weight. The patient is kept on such a diet for a week. If he becomes sugar-free by the fifth day he does not require insulin; if he is not free on the sixth day he is a borderline case; and if not by the eighth he will certainly need insulin. When the blood sugar figure, estimated after a meal and not fasting, reaches a normal level the diet is increased; Braun usually allows 30 calories per kilogram of body weight. In cases needing insulin small doses are usually given once a day, and these are gradually increased until the maximum effect, without over-insulinization, is reached with this one dose. If possible the case should be controlled with one injection daily, though it is rarely advisable to administer more than 20 units in one dose. It is wiser not to give insulin at night as hypoglycaemia may occur during sleep. The author has found that the use of insulin may safely be discontinued, dependent on the severity of the condition. If coma supervenes, as much fluid as possible should be given and insulin be injected in large doses. Carbohydrate in two forms, milk and glucose, is also advised, 1.5 grams of carbohydrate for each unit of insulin. In surgical cases the patient must be rendered free of sugar and acid bodies before operation. Insulin is nearly always essential, since mere dieting will not suffice owing to the lowered tolerance due to the suppuration.

528. **Therapeutical Value of Blood Transfusion.**

R. B. LLOYD (*Indian Med. Gaz.*, March, 1929, p. 121) defines four groups of cases in which blood transfusion is indicated: (1) acute anaemia, caused by sudden and grave haemorrhage; (2) anaemia of gradual onset; (3) haemorrhagic diseases, such as haemophilia and melaena neonatorum; and (4) general toxaemias. In the second and last groups blood transfusion is not entirely devoid of risks. In ascertaining the compatibility of different bloods, importance is attached to the procedure of direct matching. Lloyd groups separately the red cells and serums of the donor and recipient by means of stock grouping serums and cells of known groups. If the cells and serums of both prove to belong to the same group a direct match is made—that is, the serum of the recipient is tested against the donor's cells, and *vice versa*. If both these reactions are negative for agglutination, the two persons are of the same group and their bloods are compatible. Slight risks are attached to the employment of universal (Group IV) donors. Despite the great dilution of the donor's blood when

injected, the titre of the iso-agglutinin, on the presence of which the reaction depends, may be abnormally high in the case of a particular Group IV serum, and be extremely active even after dilution by the recipient's blood. This explains the occasional occurrence of severe reactions after transfusion of blood from a universal donor. Diseases may be communicated by transfusion; the most important of these is syphilis, and every donor should have his Wassermann reaction tested. Groups are inherited according to the Mendelian law, and the near relations of patients are not necessarily of the same blood group. The investigations of Happ have shown that the blood group of the infant is frequently different from that of the mother, and therefore it is unsafe to transfuse an infant from its mother without first performing grouping tests. The symptoms following incompatible blood transfusion resemble those of anaphylactic shock. The mode of action of a successful transfusion is not fully known, but, from the improvement in the red cell count, it is obvious that the action is far more than merely mechanical, and transfusion evidently acts as a powerful stimulant to the marrow. The questions as to whether the possession of a particular blood group implies any special immunity from or liability to disease, and whether the blood group ever changes, are discussed. Lloyd insists that both grouping and direct matching should always be performed where possible, but that the essential procedure is the direct match, which should never be omitted.

A Morphine Derivative.

529. W. NONNENBRUCH and E. RISCHAWY (*Deut. med. Woch.*, February 22nd, 1929, p. 305) report on the clinical uses of acetyl-dimethyl-dihydrothebaine (acedicon), which is administered by the mouth in the form of small tablets containing 0.01 gram, or subcutaneously, 1 ampoule of 1 c.cm. containing the same dose. Injected subcutaneously it is said to be free from irritation, and the effect commences within fifteen minutes. Taken by the mouth the action is less pronounced and is delayed for half an hour. Unpleasant complications are not met with. The most suitable dose was 0.01 gram, but in cases of severe pain, or if sleep was needed, 0.02 gram may be given. The drug has no noticeable injurious influence on the frequency or depth of breathing, but acts favourably on different kinds of dyspnœa. Given for cough the amount of sputum is not diminished, but the incentive to cough is lessened, and the paroxysms of coughing are rarer though stronger; it is useful in haemoptysis. In cases of diarrhœa or colitis the pain is often relieved, but the action of the bowels is not restrained. The analgesic action of 0.01 gram of acedicon subcutaneously is about the same as that of morphine, though the hypnotic action is 50 per cent. less; the cough-restraining action is similar but seems to last longer. A dose of acedicon represents four times the dose of codeine, and generally its analgesic and hypnotic action is incomparably greater than codeine. Compared with opium extract acedicon is said to have markedly less effect on the digestive tract, but its cough-restraining and hypnotic actions are greater. The sleep-inducing action of acedicon is very subject to individual idiosyncrasy; the patient is easily awakened, and without the unpleasant effects associated with morphine. Given by the mouth it rarely induced sleep.

Scarlet Fever Antitoxin.

530. N. T. WELFORD (*Amer. Journ. Dis. Child.*, March, 1929, p. 553) records his observations on 492 cases of scarlet fever admitted to the Municipal Contagious Diseases Hospital, Chicago, within a period of six months. Of these, 217 were treated with antitoxin and 275 received no serum. Approximately 60 per cent. of the severe cases showed some improvement after antitoxin, the average dose of which was 10 c.cm. intramuscularly. The incidence of complications in the group treated with scarlet fever antitoxin was 41 per cent., as compared with 32 per cent. in the group not treated with serum. When, however, the severe cases only were considered, 56 per cent. of the group treated with serum developed complications, as compared with 62 per cent. of the controls. In the mild and moderate cases no favourable effect was observed, and the use of antitoxin unnecessarily exposed the patients to the risk of severe serum reactions. The mortality rate of the severe cases in the group that did not receive antitoxin was almost double that of the group in which antitoxin was used.

Indications for Using Acetyl Choline.

531. M. VILLARET and L. JUSTIN-BESANÇON (*Med. Journ. and Record*, March 20th, 1929, p. 343) review briefly the present knowledge of acetyl choline and the conditions in which it can be beneficially used. (See *Journal*, April 13th, p. 691.) The anhydrous hydrochloride salt, stabilized with glucose, is employed, but certain precautions are necessary in its administration. It must be pure, prepared immediately before use, and its activity be physiologically controlled; it can then be safely injected subcutaneously or intramuscularly; such injections are painless and produce no local or general reactions. If given intravenously the drug is said to be dangerous, and its oral administration is useless. The chief action of acetyl choline is to lower blood pressure, but it also influences the heart, muscles, blood, and humoral equilibrium. Its therapeutic indications are numerous owing to its vaso-dilating property and to its effect on the vago-sympathetic equilibrium. The drug can be used with marked benefit in Raynaud's disease, in gangrene arising from arteritis (whether presenile, senile, or diabetic), and in other troubles of like nature; it favourably influences the arterial pressure in hypertension. The dilating property of acetyl choline has been found of value in ocular conditions due to spasm or thrombosis of the retinal artery, and in hypertonicity of the globe; it has also a remarkably effective action on the profuse sweats of tuberculosis. Owing to the way in which it modifies the calibre of the arteries and arterioles acetyl choline has been tried in angina pectoris, habitual constipation, lead colic, and in cerebral spasms (transitory hemiplegia).

Laryngology and Otology.

Osteomyelitis following Sinus Infections.

532. G. CANUYT (*Arch. Internat. de Laryngol.*, December, 1928, p. 1153) reviews the etiology, pathology, and treatment of spreading osteomyelitis of the cranial bones. The condition is rare as a post-operative complication; suppuration of the maxillary sinus, and above all of the frontal sinus, is the most frequent cause. The infection is carried along the venous system into the dura mater. Usually the case is one that has been operated on for mastoiditis, maxillary sinusitis, or more usually for frontal sinusitis. Several days after the operation the patient is found to be suffering from fever, acute headache, and abundant suppuration. Further intervention is resorted to, but the infection spreads to neighbouring bones and, by the formation of extradural abscesses, leads to meningitis, septicæmia, or encephalitis, which nearly always terminates fatally. Bacteriological examination shows a varied flora—streptococci, staphylococci, pneumococci, and enterococci—but the infection is chiefly streptococcal in origin. The number and perfect formation of the streptococcal chains were marked features of the author's cases, and the organisms were of the haemolytic variety. Canuyt points out the value of radiography in these cases as showing the extent to which necrosis has attacked the cranial bones. He also used vaccino-therapy in all his cases, both by subcutaneous injection and local application to the seat of the infection. Large doses of antistreptococcal serum were tried without result, and treatment with salts of silver and iodine also proved valueless. The author adds that he has no experience of deep radiotherapy which may be worth trying. Surgical treatment consists in keeping the maxillary and frontal sinuses well opened and drained. Retention of pus is to be avoided at all costs, but once the sutures have been passed by the invading infection further surgical interference is of no avail.

The Physiology of Vestibular Reflexes.

533. A. C. IVY (*Arch. of Otolaryngol.*, February, 1929, p. 129) reviews recent work on the physiology of vestibular reflexes as shown by movements of the eyes, and records the view held now that the slow component, or deviation, is due entirely to stimulation of the vestibule. Considerable doubt has been thrown on the part played by the semicircular canals in the production of deviation. The canals have been ligatured, removed, and their position has been altered, but the response to stimulation has remained the same. The more modern theory is that the changes in inertia of fluid in the utricle cause changes of pressure and tension in the cristæ of the ampullæ and thus provoke the deviation of the eyeballs. The nystagmus is controlled by some subcortical centre—probably in the oculo-motor group—over which the cerebrum exerts control. It is possible that the deviation of the eyeball stimulates sensory nerve endings in the orbit and that these provoke the quick return. It has been shown that both deviation and nystagmus occur after decerebration, and that nystagmoid movements are more marked after hemidecerebration when the deviation is to the side opposite to the lesion. When deviation is to the same side as the lesion nystagmus is either absent or reduced. These results confirm the finding that the cerebrum exerts an inhibitory action on nystagmus.

534. The Tonsil and Throat Infections.

A. DELLA CIOPPA (*Rif. Med.*, January 26th, 1929, p. 131) has examined 220 children (120 boys and 100 girls) between the ages of 4 and 12, in the antituberculosis institute in Naples, and has noted the normal and abnormal conditions of their tonsils in relation to the presence of lymphadenitis of the neck, more especially of the suprahyoid region and the angle of the maxilla, and their predisposition to tuberculosis. He found the tonsils were normal in 23 per cent., but hypertrophied in 77 per cent. Of those with normal tonsils, 43 per cent. showed cervical lymphadenitis and 27 per cent. with suprahyoid adenitis. Of those with abnormal tonsils, 92 per cent. had cervical adenitis and 86 per cent. infection of the suprahyoid glands. In the 51 cases with normal tonsils there were adenoid growths in the nasopharynx in 19 (37 per cent.), and among the 169 with abnormal tonsils 107 (63 per cent.) had adenoid growths. Among the 51 normals, 11 (24 per cent.) gave positive Pirquet reactions, and among the 169 abnormal tonsils 80 (51 per cent.) were Pirquet positive. The high percentage of lymphadenitis and positive Pirquet reactions met with in those children with abnormal tonsils indicates the importance of inflammation of the tonsil in relation to invasion by tuberculosis.

535. Diagnosis of Disease in the Paranasal Sinuses.

R. H. FRASER (*Radiology*, January, 1929, p. 6) dilutes lipiodol with paraffin or olive oil, reducing it to 14 per cent. iodine content, for sinus use. The two main methods of introducing the oil are direct injection and suffusion; the former is used most frequently, particularly following irrigation for discharge, in chronic suppuration of the maxillary antrum. Complete fillings are obtained. The indirect method, in which the nasal fossa is used as a reservoir from which to fill the sinuses by gravity, the patient's head being more or less inverted, is advisable for ethmoid, frontal, sphenoid, and early maxillary antrum cases. Evidence is obtained of choked sinus or filling defect, or delayed emptying. From a purely roentgenographic point of view the lipiodol method (1) reveals incipient changes earlier, demarcating soft tissue growths; (2) multiplies the number or extent of separation lines, rendering them capable of interpretation; (3) results in the reporting of thicknesses and masses as well as density.

Obstetrics and Gynaecology.

536. Circulatory Changes in Pregnancy.

D. C. HARE and M. N. KARN (*Quart. Journ. Med.*, April, 1929, p. 381) record the results of a clinical investigation of the blood pressure, pulse rate, and response to exercise during normal pregnancy, with some observations after confinement. Most of the patients were examined several times at about monthly intervals, while other records were from patients seen only once, 106 making 468 attendances and 145 being seen once or twice only. A more limited study during the six months following confinement was based upon 203 records. The conditions of examination were uniform, the patients being seen in the morning, and, after resting recumbent for twenty minutes, the pulse rate and right and left arm readings of the blood pressure were recorded. These observations were repeated after sitting upright for five minutes, and the pulse rate standing was then taken for two consecutive minutes in four half-minute records. A light exercise test was made by stepping to a metronome thirty times in sixty seconds on to a stool seven inches high, moving the feet consecutively (right up, left up, right down, left down) so that the whole body weight was raised and lowered to complete one step. Four half-minute counts of the pulse were then taken with the patient sitting. The average systolic pressure of healthy pregnant women was found to be lower than that of non-pregnant women, with a tendency to a lower pressure in the middle period than in the early weeks, and a slight rise in the last three months, any considerable rise being associated with the onset of some toxic condition. No significant difference was found between the mean diastolic pressure in pregnant and in non-pregnant women. The pulse pressure is lower than that of non-pregnant women, and falls as pregnancy advances; the pulse rate is not significantly altered, and after exercise does not differ from the controls. No evidence was noted of embarrassment of the circulation during the later months of pregnancy. The authors state that the mean systolic pressure remains during the first week after parturition at the same level as in the last months of pregnancy, subsequently reaching a low mean and returning slowly to the control figure; the diastolic pressure falls to normal from the raised figure of the last weeks of pregnancy and varies but little subsequently. The mean resting pulse rate following parturition becomes lower than at any period of pregnancy, and remains below the control figure.

537. Prevention of Cancer of the Cervix.

R. R. HUGGINS (*Amer. Journ. Obstet. and Gynecol*, April, 1929, p. 589) contrasts the reduction in tuberculosis mortality with the slight increase in cancer and the little change in puerperal sepsis. He attributes this failure in dealing with cancer and puerperal sepsis to a lack of understanding and appreciation of the causative factors. He urges that problems relating to the cervix should be surveyed from the viewpoint of preventive medicine. In the region of the cervix the epithelium is of four types. The secretion from the uterine body differs from that of the cervix, and accordingly infection may differ in its effects in these two situations. While normally the cervical mucosa is impervious to organisms, the minor injuries of labour cause an epithelial displacement. Cells which in the healthy state are bathed in an alkaline medium, in disease are swamped in a strong acid which assists a coincident infection in producing an erosion. Huggins believes that subinvolution, though due sometimes to uterine infection, may also result from cervical spread, and he advises that every puerperal patient should be kept under observation until the cervix is healed. Students should be carefully taught the pathology of erosion, should be able to identify microscopically the changes which precede malignancy, and should be fully conversant with the appearances of early malignancy. Irritation, in the form of an acid secretion playing on a cervical erosion, may be an important factor in the etiology of cervical carcinoma; and in this connexion Huggins points out that the changes present in the cervix, resulting from injury, irritation, and chronic inflammation, differ very little from those of early cancer. Hunner's method of treatment by cauterization is highly commended. In cases where the cervical infection is deep-seated and chronic the entire area must be excised under anaesthesia with a cautery or an endotherm knife. In the last ten years he has treated 2,985 chronic cases in this way, and in the series there has been no case of cervical carcinoma. Acute erosion is treated by the small cautery without an anaesthetic. In conclusion, he states that 85 per cent. of women who had borne children have cervicitis, and it is by treating the cervix carefully in the puerperium and afterwards that carcinoma cervicis and puerperal sepsis will very probably be lessened.

538. Uterine Evacuation under Spinal Anaesthesia.

P. BALARD and R. MAHON (*Gynécol. et Obstét.*, February, 1929, p. 91) report six cases in which the cervix was manually dilated under spinal anaesthesia, and the method of Delmas employed with immediate delivery of the child following internal version. Under spinal anaesthesia the cervix can be dilated fully with subsequent extraction of the child, even when the patient is not in labour. The indications for intervention in the six cases recorded were: placenta praevia in two cases; pelvic contraction in two cases; albuminuria in one case; and prolapse of the cord in the last case. There were five foetal deaths, but the authors believe that the results would have been the same in this respect had any other method been adopted. They point out that in three cases where the weight of the child exceeded 4 lb. severe cervical laceration, extending into the vaginal vault, occurred, and also that the ease with which version was performed depended largely on the size of the child and on the amount of fluid in the uterus. The puerperium was normal in all, but the authors point out the consequences that might result from injuries to the soft parts, such as their patients received. According to Balard and Mahon this method is not one of choice for the contracted pelvis either in a primipara or a multipara. In cases of prolapsed cord, with the cervix practically closed, it should only be preferred to a low Caesarean operation if conditions are unsuitable for the latter. In cases of central placenta praevia it should only be used when dealing with a premature child, and when the maternal blood pressure is not too low to be a contraindication. Lastly, in cases of albuminuria, where the life of the child may be already in jeopardy, and where the maternal blood pressure is high, Delmas's method seems very commendable.

539. Neo-natal Sequels of Maternal Pyelitis.

F. VOZZA (*Ann. di Ostet. e Ginecol.*, March, 1929, p. 251) remarks that although *B. coli* pyelonephritis in pregnancy is accompanied in about one-quarter of cases by premature labour and foetal death, little is known of the pathology of the infants who survive such conditions. A certain number of cases have been recorded in which infants born of mothers suffering from pyelitis have manifested *B. coli* septicaemia or *B. coli* infections of the gastro-intestinal tract, and in the present paper three instances are described in which the infants suffered from ophthalmia due to a colon bacillus morphologically, biologically, and culturally identical

with that recovered from the maternal urine. The conjunctivitis, which was attended with much palpebral oedema and pus formation, was noted from the twenty-fourth to the forty-eighth hour after birth; it yielded readily to treatment by lavage and instillations of protargol or zinc sulphate. Vozza concludes that a transplacental transference of *B. coli* in these cases is improbable, and that the conjunctiva was infected either from the liquor amnii (in one case *B. coli* was obtained in almost pure culture from the purulent lochia) or directly from the urine involuntarily voided during childbirth. In two cases, however, prophylactic instillation of silver nitrate into the conjunctival sacs had been carried out in the routine way after the birth.

Pathology.

540. The Basal Metabolism in Hypertension.

E. HAYASAKA (*Tohoku Journ. of Exper. Med.*, February 15th, 1929, p. 270) reviews the question of the basal metabolism in patients with raised blood pressure, and gives an account of the research work on this subject conducted by him in the laboratory of Professor Kato's medical clinic at the Tohoku Imperial University. The estimation of the metabolism was carried out by means of Benedict's portable respiration apparatus, and the results are shown in percentages of the normal values prepared by Sanborn. Controls were taken of seven normal subjects and of ten mild cases (gastritis, neurasthenia) with normal blood pressure. The normal subjects approximated Sanborn's standards; the mild cases showed an average basal metabolic rate of − 15.9. In fourteen cases of benign hypertension the rate was occasionally slightly increased, the average being − 6. In six cases of malignant hypertension the basal metabolic rate was increased, the average being + 18. In these cases the systolic blood pressure ranged from 181 to 270 mm. Hg, and there was definite hypertrophy and dilatation. It was found that in the same individual the basal metabolic rate varied almost proportionately to the blood pressure. In seven cases of secondary contracted kidneys there was a reduced rate (average − 14), but in the uraemic state this rose to + 27. No definite relation was found between the basal metabolic rate and the retention of non-protein nitrogenous substances in the blood. The author concludes that in patients with hypertension, whose renal function remains normal, the basal metabolism may be almost normal, while in the majority of cases of hypertension, in which the renal function is injured (primary and secondary contracted kidney), it is apparently changed.

541. Cancer and Tuberculosis.

T. CHERRY (*Med. Journ. of Australia*, February 9th, 1929, p. 160) has collected statistical evidence supporting the view that with few exceptions a high or low incidence of pulmonary tuberculosis between the ages of 25 and 45 was followed by a corresponding high or low incidence of cancer in all subsequent age periods, and that in all deaths above the age of 25 in each successive five-year period the combined deaths from the two diseases have always constituted 20 per cent. of the total deaths, the increase in cancer compensating for the reduction in phthisis. These facts suggested to Cherry the idea that cancer might attack those persons who were hyper-resistant to tuberculosis, and that the factor which precipitated the crisis in the life-history of the cells of the body was a fresh invasion by the bacillus. A series of experiments was made along the lines of this theory, mice being used as the test animals, since they are liable to spontaneous cancer and are also highly resistant to tuberculosis. After the inoculation of small numbers of tubercle bacilli beneath the cuticle, the 6 per cent. incidence of tumours in these mice rose to 55 per cent. in the males and 71 per cent. in the females. About one-third of these tumours were mesoblastic and two-thirds epithelial. In type and situation these neoplasms differed materially from any hitherto recorded in mice. Tumours were found in the thyroid, pylorus, colon, pancreas, prostate, and bladder, organs in which they had never been observed in this animal. The mice also exhibited an associated syndrome of lymphoid changes; the relationship of these to leukaemia and pseudo-leukaemia and to lympho-sarcoma, and the etiology of the condition, are discussed. Death occurred on the average in eight and a half months after inoculation. The results, so far as diversity of type is concerned, approximated more nearly to cancer in man, particularly with regard to the selection of the pylorus by nearly half the tumours. These facts, Cherry thinks, afford strong presumptive evidence that the tubercle bacillus was the indirect but essential agent in the promotion of neoplastic growth in the mice.

542. Cultivation of the Foot-and-mouth Virus.

P. RINJARD and Mlle CORDIER (*C. R. Soc. de Biologie*, April 19th, 1929, p. 977) describe a method by which they have been able to cultivate the virus of foot-and-mouth disease in the sheep. It consists in producing an artificial oedema by the injection of croton oil into the subcutaneous tissues, and thus providing a suitable medium in which the virus is able to multiply. Their technique was as follows. Into the right side of the thorax of a sheep they inoculated 100 c.cm. of saline, four drops of croton oil, and 5 c.cm. of serum taken from a guinea-pig which had been inoculated with foot-and-mouth virus, and the blood of which was shown to be virulent. Into the left side they inoculated saline and croton oil, but no virus. Twenty-four hours later blood was taken from the jugular vein of the sheep and lymph from each site of inoculation, and titrated for virulence on a number of guinea-pigs. A similar titration was repeated twenty-four hours later, when the animal was killed. The results showed that at the twenty-fourth hour the lymph from the right side alone was virulent. At the forty-eighth hour the lymph from the right side was infective in a dilution of 1/400; the lymph from the left side in a dilution of 1/4, but not in 1/400; the blood proved virulent, but in what dilution is not stated. It would appear, therefore, that the virus, introduced in the form of guinea-pig's serum, is able to multiply abundantly in a sterile oedema, and may invade the blood stream. The authors hope that by this method it will prove possible to cultivate the virus in a pure condition in large quantity.

543. Effects of Massive Doses of Irradiated Ergosterol.

I. J. KLEIN (*Journ. Amer. Med. Assoc.*, February 23rd, 1929, p. 631), having produced rickets in albino rats with a low phosphorus rickotogenic diet, placed them in three groups. One group, which served as the control, was exposed to reflected daylight. The second group received, in addition, 2 per cent. cod-liver oil. The third group was given daily 20,000 to 100,000 times the dose of irradiated ergosterol in sesame oil necessary to cure rickets. The experiment lasted for one month, during which the rickotogenic diet was continued. The author found these massive doses of ergosterol caused: (1) anorexia and loss of weight; (2) the blood calcium concentration to be 50 per cent. higher than in the other two groups, while the phosphorus remained approximately the same; and (3) the protein concentration of the serum to be less and the albumin-globulin ratio higher than in group (2). The bones of all the animals in group (3) were healed, but the results indicate that these greatly excessive doses did harm.

544. M. COMEL (*Biochemica e Terapia Sperimentale*, March 31st, 1929, p. 81) has observed the effects of large doses of irradiated ergosterol administered subcutaneously to healthy and to rachitic rats. Rickets was induced by MacCallum's diet No. 4025. After five weeks' feeding, six severely rachitic rats, of which three were more than 5 weeks old, were given 5 mg. of a 1 per cent. solution of irradiated ergosterol subcutaneously on alternate days, receiving in all seventeen injections. They soon reacted to the treatment, and after twenty days showed no signs of rickets either clinically or radiographically, and increased by two-thirds of their original weight. A control group of rats, healthy and of the same age, received the same dose, and similarly increased in weight. Two groups of older rats (three months), one healthy, the other with induced rickets, were given 10 mg. of radiated ergosterol subcutaneously on alternate days, receiving in all ten doses; the animals showed no ill effects and increased in weight. One of the healthy group gave birth to young which were unaffected by this enormous dose of ergosterol. The author finds that the doses employed had no injurious or toxic action, but there was a marked curative and calcium-fixing effect. There was no evidence of precipitation of insoluble calcium salts in the tissues and organs.

545. Bacteriology of Epidemic Sore Throat.

E. S. ROBINSON (*Journ. Bacteriol.*, January, 1929, p. 53) compared the streptococci isolated from patients suffering from epidemic sore throat with those isolated from the milk of a cow which was suspected of being responsible for the outbreak. Both organisms were capsulated haemolytic streptococci, which produced acid in glucose, lactose, sucrose, and salicin, but not in [illegible] inulin, or raffinose, and which belonged to the lo[illegible]oup (pH 5.3-5.7) in glucose broth. Be[illegible] virulent for mice. There appeared to be no difference between the human and the bovine strains, and there seemed to be little doubt that the cow's milk was responsible for the human epidemic.

EXTRA PHARMACOPŒIA

Revised by W. H. MARTINDALE, Ph.D.

Conveys the latest information in Therapy, Chemistry, Pharmacy, etc.

ARSENIC and BISMUTH COMPOUNDS: In syphilis, etc. DIGITALIS: New preparations for use per os and by injection. EPHEDRINE in asthma. HEXYL-RESORCIN: The new urinary antiseptic. INSULIN and substitutes in diabetes. COLLOIDAL LEAD on trial in malignant disease. QUINIDINE in auricular fibrillation. SULPHUR INJECTIONS in chronic rheumatism. SALICYLIC DERIVATIVES, e.g., Methyl-Aspriodine. VITAMINS: Production of anti-rachitic factor, etc. LIVER DIET treatment of pernicious anæmia and latest work on Pituitary, Ovarian Hormones, Thyroid, Thyroxin, etc.

BRITISH MEDICAL JOURNAL: "An accurate and convenient summary of up-to-date knowledge regarding the innumerable drugs and preparations that are to-day offered to the physician for his use."

LANCET: "This remarkably handy compilation of necessary information will obtain as on previous occasions a large circulation. For ourselves its possession is a necessity."

PRACTITIONER: "Our examination proves that what we expected is fulfilled, namely, that nothing of value has been overlooked. . . . The value of the Extra Pharmacopœia is greater than ever—if that be possible."

PRESCRIBER: "It is a mine of information and should be on the desk of every physician and pharmacist."

MED. PRESS: "The practitioner and the chemist will find in its pages the very latest information they require."

PHARMACEUTICAL JOURNAL: "The supreme value of the E.P. is that (as through a periscope) it enables the physician and pharmacist to see in any part of the whole circle within which he works what is outstanding and essential."

CHEMIST AND DRUGGIST: "We take it for granted that every up-to-date pharmacist will hasten to possess so indispensable a book."

de KUYPER'S

HOLLANDS

Distilled from genuine malt liquor with the Juniper berry added. The advantage gained by distilling the berry with the spirit is the production of a preparation of Oleum Juniperi, mellow and free from irritating properties.

Oleum Juniperi is official in the British Pharmacopœia, and is described as carminative, anti-spasmodic, and a stimulating diuretic.

In this form, therefore, the oil of Juniper can be safely taken with regularity.

Distilled by the same family for 233 years.

4 big advantages

DONIGER Krome-Plate Surgical Instruments possess four big advantages over ordinary nickel-plated instruments. They are:

(a) much harder and stronger;
(b) rust-resisting;
(c) last five times as long as nickel;
(d) retain their original brightness.

These are facts that have been proved under practical conditions in many important hospitals and clinics in America where Doniger Instruments are used consistently.

Doniger Instruments are made from high carbon steel specially polished to ensure perfect smoothness, then nickel-plated, and finally given a generous coating of chromium. Despite the high quality of the materials and craftsmanship employed, Doniger Instruments cost only a fraction more than nickel-plated instruments.

You are invited to apply to your usual Supply House for full particulars and prices.

Doniger Instruments are not supplied direct to the Profession.

THE POSTAL ACCOUNT

It is often supposed that to live a long way from the nearest branch of a bank, or to be constantly unable to go to the bank in person, is a handicap to the enjoyment of the full advantages which, it is admitted, a banking account offers. Perhaps it is assumed that to conduct an account by post involves 'more letter writing', or is costly, or is not welcomed by the Bank. It is the aim of the Westminster Bank to dispel such misconceptions by a leaflet entitled *The Postal Account*, which explains the convenience of the method, and offers some clear suggestions.

The Secretary of the Bank will be pleased to send a copy on application

THE RESIDENTIAL TREATMENT OF ALCOHOLISM & DRUG ADDICTION

RENDLESHAM HALL

(Postal Address)—WOODBRIDGE, SUFFOLK.

Rendlesham Hall, which is open to receive patients, is essentially a Sanatorium. Its daily life and routine are that of an ordinary comfortable holiday or health resort, or of a large country house. Each patient has all the privileges of a guest consistent with the prescribed medical treatment.

Rendlesham Hall has 45 bedrooms, and about 450 acres of gardens and park. It has also a private nine-hole golf course, tennis and croquet lawns, and bowling green.

Illustrated Booklet, giving particulars as to terms, etc., can be had on application to the

RESIDENT MEDICAL SUPERINTENDENT.

Telegrams and Telephone: Wickham Market 16.

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS, NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical baths, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The Seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc

For terms and further particulars apply to the Medical Superintendent (Telephone: No 56 Northampton), who can be seen in London by appointment.

UNIVERSITY OF LONDON.

EXTERNAL EXAMINERSHIPS, 1930.

The Senate announce the following vacant External Examinerships for all Examinations above Matriculation for the year 1930. Except when otherwise stated, Examiners will act in all Examinations in which the subject is included.

The Examiners for the Final Examinations will be invited as occasion arises to take part in the Higher Examinations, but the Senate have resolved that in certain cases in which the work is heavy they shall not be required to do so.

For the First Examination for Medical Degrees.
Biology. Chemistry. Physics.

For the Second Examination for Medical Degrees.
Anatomy (two). Pharmacology. Physiology.
NOTE.—One of the two Examiners appointed in Anatomy will be required to act for Science Examinations also.

For Final and Higher Examinations for Medical Degrees.
Medicine. Surgery (two). State Medicine.

Associate Examiners.

Applications will also be invited for Associate Examiners in Medicine, Obstetric Medicine, Pathology, and Surgery. A separate application form must be used for Associate Examinerships and the word "Associate" must be written on it.

Application form (or forms if more than one Examinership is applied for) and particulars of the remuneration and duties can be obtained from the External Registrar.

Candidates must send in their names to the External Registrar, GEO. F. GOODCHILD, M.A., B.Sc., with any attestation of their qualifications they may think desirable on or before Monday, July 7th, 1929. (Envelopes should be marked "Examinership.")

The Senate desire that no application of any kind be made to individual members.

If testimonials are submitted one copy only of each is required. In no case should original testimonials be submitted. If more than one Examinership is applied for a separate and complete application must be forwarded in respect of each Examinership. The appointments will be made by the Senate in November. Applicants who desire that the result should be communicated to them are requested to enclose a stamped and addressed envelope with their applications.

University of London, South Kensington, S.W.7. T. FRANKLIN SIBLY, Principal.

F.R.C.S. (Edin.).

A TUTORIAL CLASS, with Museum Demonstrations, for the next Examination will commence shortly. Correspondence tuition if desired.—FRED GRAHAM, M.D., F.R.C.S.(Edin.), Surgeons' Hall, Edinburgh.

UNIVERSITY of CAMBRIDGE.

DIPLOMA IN MEDICAL RADIOLOGY AND ELECTROLOGY (D.M.R. & E.).

The Course of study for the Diploma, which is open only to duly qualified medical men and women, begins on October 1st, 1929, and occupies nine months. The examinations consist of three parts:

1. Physics, with examinations in January and April.
2. Radiology and Electrology, with examinations in April and July.
3. The presentation of a thesis or exercise which is entirely the candidate's own work, and is intended to show that he has had practical experience of the subjects.

The first three months may be spent either in Cambridge, where the Physics is done in the Cavendish Laboratory and the Radiology and Electrology in a specially equipped Department of Radiology, or in London, where the Physics is done in the Laboratories of the Middlesex Hospital and King's College and the Radiology and Electrology is taught at the British Institute of Radiology. These Courses run concurrently in Cambridge and London.

The second three months must be spent in London, where courses of lectures are given at the British Institute of Radiology, and are combined with clinical instruction in the large teaching hospitals.

The third three months may be spent in recognized hospitals in London or elsewhere, the student acting as clinical assistant or in similar capacity.

Further information as to the Courses may be obtained from:

G. STEAD, M.A., Secretary for the Diploma, and Lecturer in Physics as applied to Medical Radiology, Cavendish Laboratory, Cambridge.
A. E. BARCLAY, O.B.E., M.A., M.D., Lecturer in Radiology, Department of Radiology, Medical School, Cambridge.
The Director of the British Institute of Radiology, 32, Welbeck St., London, W.1.

Society of Apothecaries of London.

MASTERY OF MIDWIFERY EXAMINATION.

The next Examination will take place on Monday, November 18th, and following days. For regulations apply to—
FRANK HAYDON, Secretary.

All Saints' Hospital (For Genito-URINARY DISEASES),

49/55, Vauxhall Bridge Road, S.W.1.

THE MEDICAL AND DENTAL DEFENCE UNION OF SCOTLAND, LIMITED.

Secretaries and Registered Office: Millar, Thomson & Dunlop, C.A., 113, St. Vincent Street, Glasgow.

ANNUAL SUBSCRIPTION £1. ENTRANCE FEE 10/-.

No entrance fee to those joining within 12 months of obtaining qualification. Benefits include defence of claims for alleged negligence in professional work, including indemnity of £2,500 and costs, and advice on professional difficulties.

Particulars and forms of application can be obtained from the Secretaries at the above address.

Lancashire County Council.

SCHOOL MEDICAL AND CHILD WELFARE DEPARTMENT.

APPOINTMENT OF THREE ASSISTANT COUNTY MEDICAL OFFICERS.

The Lancashire County Council invite applications from registered medical practitioners for the post of Assistant County Medical Officer.

Applicants must not be over 35 years of age, and must possess the Diploma of Public Health.

The duties of the post include the Medical Inspection of School Children; work under the Maternity and Child Welfare Acts; general Public Health work; and such other duties as may from time to time be imposed by the County Council.

The persons appointed will be required to devote their whole time to the service of the County Council. The salary will be £800 a year, rising (subject to satisfactory service) by annual increments of £50 to a maximum of £1,000 a year, together with first-class railway fares and other reasonable expenses.

The persons appointed will be required to pass a medical examination, and to contribute to the Council's Superannuation Fund.

Applications must be made upon a form which can be obtained, together with further particulars, from the County Medical Officer of Health, School Medical and Child Welfare Department, County Offices, Preston, to whom the completed forms should be returned not later than Saturday, June 15th. All communications must be endorsed "Assistant County Medical Officer."

Any form of canvassing is strictly forbidden, and will disqualify.

County Offices, Preston. May, 1929. GEORGE ETHERTON, Clerk of the County Council.

Lancashire County Council.

Applications are invited for the post of JUNIOR HOUSE SURGEON (woman) at the above Hospital, which contains 87 beds. Salary is at the rate of £150 a year, together with board, residence, and laundry.

The appointment will be for a period of six months in the first instance, and for a further period of six months at the option of the Council.

Candidates must be duly qualified and registered. Preference will be given to candidates who have held resident Hospital appointments, and who are competent Anæsthetists.

Applications, with copies of two recent testimonials, should be sent not later than June 15th to Dr. J. J. BUTTERWORTH, School Medical and Child Welfare Department, County Offices, Preston.

GEORGE ETHERTON, Clerk of the County Council.

City of Birmingham.

FOURTH ASSISTANT MEDICAL OFFICER required at the CITY HOSPITAL FOR INFECTIOUS DISEASES, LITTLE BROMWICH. Previous resident Hospital post essential. The appointment will be made for 12 months only. Duty to commence not later than August 1st.

Salary £300 per annum, together with board, residence, and laundry.

Forms of application may be obtained from the Medical Superintendent, and should be returned to him on or before Saturday, June 15th.

Norfolk and Norwich Hospital,

NORWICH. (350 Beds.)

Applications are invited for the post of HOUSE SURGEON Salary £120 per annum, with board, residence, and laundry. Preference will be given to a candidate who has held a previous Hospital appointment. Candidates (male), who must possess registered qualifications, should forward applications, stating age, nationality, etc., together with copies of testimonials, to the undersigned, not later than Tuesday, June 11th.

June 1st 1929. FRANK INCH, House Gov. & Secretary.

Lancashire County Council.

APPOINTMENT OF ASSISTANT TUBERCULOSIS MEDICAL OFFICER for HIGH CARLEY SANATORIUM, Near ULVERSTON.

The Lancashire County Council are prepared to receive applications for the post of Male Assistant Tuberculosis Medical Officer (unmarried) for the High Carley Sanatorium (112 beds). Salary £450, rising by two annual increments of £25 to £500 per annum, together with the following emoluments: board, furnished apartments, fuel, light, and laundry.

Applicants must be registered medical practitioners between 25 and 34 years of age, and the person appointed must devote the whole of his time to the duties as defined by the Council. Candidates must have held House appointments for at least six months in a General Hospital, and have had special experience in the diagnosis and treatment of Tuberculosis.

The possession of a Diploma in Public Health and practical experience in X-ray work will be deemed additional qualifications for the post.

Contributory Superannuation Scheme is in operation, with medical examination for entrants.

Forms of application, terms of appointment, and list of duties can be obtained from the undersigned. Closing date June 10th. All letters must be marked on the outside "Assistant Tuberculosis M.O."

County Offices, Preston. GEORGE ETHERTON, Clerk of the County Council.

County Borough of Birkenhead.

MEDICAL OFFICER'S DEPARTMENT.

ASSISTANT MEDICAL OFFICER (Resident).

Applications are invited for the above appointment from duly qualified men (unmarried) holding a Diploma in Public Health, who have had experience as residents in Hospitals for Infectious Diseases.

The appointment carries with it a salary of £450 per annum, residence at the Infectious Diseases Hospital, board and washing.

The successful candidate will be required to pass a medical examination, and a deduction of 5 per cent. will be made from salary towards the Council's scheme under the Local Government and Other Officers Superannuation Act, 1922.

e will be required to undertake the treatment of patients in the Hospital, to assist at the Municipal Venereal Diseases Clinic, and to carry out such other duties as may be assigned to him by the Medical Officer of Health.

Canvassing members of the Town Council, either directly or indirectly, will disqualify.

Particulars of the appointment and form of application may be obtained from D. MORLEY MATHIESON, Esq., M.A., M.D., Medical Officer of Health, 9, Hamilton Square, Birkenhead.

Applications must be received not later than *June 17th.*

Town Hall, Birkenhead. May 22nd, 1929. E. W. TAME, Town Clerk.

Salop County Council.

MEDICAL INSPECTION OF SCHOOL CHILDREN AND MATERNITY AND CHILD WELFARE.

Applications are invited from registered medical practitioners (male) for the post of ASSISTANT MEDICAL OFFICER to work under these Schemes. Salary £600 per annum, rising by annual increments of £25 to a maximum of £700, with travelling and out-of-pocket expenses on a fixed scale.

The salary will be subject to a deduction of 5 per cent. for Superannuation under the Local Government and Other Officers Superannuation Act, 1922, and the candidate selected will be required to pass a medical examination.

Candidates must possess a Diploma in Public Health, and experience in Refraction work will be considered an important additional qualification.

Applications should be received on or before Saturday, June 8th, by the County Medical Officer of Health, College Hill House, Shrewsbury, from whom forms of application, conditions of appointment, list of duties, and any other information can be obtained.

Birmingham Union.

SELLY OAK HOSPITAL.

CASUALTY OFFICER (Male).

'rom fully qualified
he appointment of
t the Selly Oak

mmodation is 550
Medical, General
Surgical, Gynæcological, Obstetrical, Children and Infectious sections. There is a completely equipped Pathological Laboratory, also X-ray, Electro-therapeutic, Massage, and Sunlight Departments. Over 2,500 operations are performed annually.

The appointment will be for a period of six months in the first instance, but may be extended at the end of that time.

The person appointed will be required to assist at operations, administer anæsthetics, and undertake casualty work, and such other duties as may be assigned to him by the Medical Superintendent, and, should occasion arise, to assist at any of the other Institutions under the control of the Guardians.

The salary attached to the appointment is at the rate of £200 per annum, together with full residential emoluments (rations, apartments, laundry, and attendance)

\ deduction of 2 per cent. will be made from the salary and value of emoluments under the provisions of the Poor Law Officers Superannuation Act, 1896, and for this purpose the emoluments are valued at £200 per annum.

Further particulars of the appointment may be obtained from the Medical Superintendent, Mr. R. P. STANLEY KELMAN, M.B., F.R.C.S. (Eng. and Edin.) at the Selly Oak Hospital.

Applications, stating age, experience, and qualifications, accompanied by copies of recent testimonials, must be forwarded so as to reach me not later than Wednesday, June 12th.

Union Offices, Edmund Street, Birmingham. May 24th, 1929. C. P. BEECH, Clerk to the Guardians.

Northamptonshire.

TUBERCULOSIS OFFICER.

The Northamptonshire County Council invite applications for the appointment of Tuberculosis Officer.

The salary will be at the rate of £750 per annum, together with offices, clerical assistance, stationery, and such allowances for travelling and other necessary out-of-pocket expenses as the County Council shall from time to time approve. A periodical review of salaries is made by the County Council, and suitable increments of salary will be given for proved ability and satisfactory service.

The salary will be subject to a deduction of 5 per cent. per annum for superannuation, in accordance with the provisions of the Local *Government and Other Officers Superannuation* Act, 1922, which the County Council have adopted. The candidate appointed will be required to pass a medical examination.

The officer appointed must reside at a place to be approved by the County Council and devote the whole of his time to the service of the Council.

The officer appointed will be independent clinically, but administratively is on the staff *of the Public Health Department under the* County Medical Officer of Health. The duties include the charge of the Tuberculosis Dispensaries, and of the care, otherwise than in sanatoria, of persons suffering from or suspected of tuberculosis. The Council maintains its own sanatorium and a Resident Medical Officer is in charge thereof.

The appointment is subject to the approval of the Ministry of Health, and is determinable by three months' notice on either side.

Canvassing will disqualify.

County Hall, Northampton. H. A. MILLINGTON, Clerk of the County Council.

Metropolitan Asylums Board.

APPOINTMENT OF BACTERIOLOGIST AT THE BOARD'S ANTITOXIN ESTABLISHMENT.

The Board invite applications for the appointment of Bacteriologist at their Antitoxin Establishment, Belmont Laboratories and Stables, Sutton, Surrey.

The candidate appointed will be responsible, under the Director, for the Bacteriological and Serological work of the laboratories. He will be required to make himself acquainted with the general running of the laboratories, and so be in a position to take charge, when required; and also, subject to the approval of the Director, to carry out research in connection with the work of the laboratories.

Candidates must be qualified by law to practise Medicine and Surgery in England, and should possess a sound knowledge of "immunity" and practical acquaintance with immunological methods.

The commencing salary is at the rate of £700 per annum.

Application forms containing full particulars of the appointment may be obtained, by sending stamped addressed foolscap envelope, from the Clerk, Metropolitan Asylums Board, Victoria Embankment, London, E.C.4, to whom completed applications must be returned not later than 10 a.m. on Wednesday, June 19th.

ALLAN POWELL, Clerk to the Board.

Metropolitan Asylums Board.

INFECTIOUS HOSPITALS SERVICE.

APPOINTMENT OF ASSISTANT MEDICAL OFFICERS.

Applications are invited for appointments as Junior Assistant Medical Officers in the Infectious Hospitals Service.

Candidates must not exceed 30 years of age, and must be duly registered and qualified by law to practise both Medicine and Surgery in England. Junior Assistant Medical Officers are subject to annual re-election.

Salary £500 per annum. Married quarters are not available.

Assistant Medical Officers are required to reside in the Hospitals, and to pay for board, lodging, and washing at the rate fixed from time to time by the Board's Finance Committee. At present the rate is £130 per annum.

Application to be made not later than 10 a.m. on Wednesday, June 19th, on form obtainable by sending stamped addressed foolscap envelope to the Clerk, Metropolitan Asylums Board, Victoria Embankment, London, E.C.4.

ALLAN POWELL, Clerk to the Board.

Metropolitan Asylums Board.

The Board invite applications for appointment as JUNIOR ASSISTANT MEDICAL OFFICER in their Mental Hospitals Service. Salary £500 per annum, rising after three years' approved service to £560. Candidates must be under 40 years of age, and should hold, or should be prepared to undertake to read for, the Diploma in Psychological Medicine. The appointment is renewable annually and is made in the first instance to March 31st, 1930.

If the candidate appointed is required to reside in the Institution to which he is allocated, a charge fixed by the Board's Finance Committee will be made for such residential allowances as may be authorised.

Forms of application may be obtained by sending stamped addressed foolscap envelope to the Clerk to the Board, Metropolitan Asylums Board, Victoria Embankment, E.C.4, to whom they should be returned not later than June 12th.

ALLAN POWELL, Clerk to the Board.

Metropolitan Asylums Board.

The Board invite applications for appointment as JUNIOR ASSISTANT MEDICAL OFFICER in charge of the Out-Patient Department for duty at QUEEN ELIZABETH HOSPITAL FOR CHILDREN, CARSHALTON, SURREY. A considerable proportion of the cases received are of an orthopædic nature. Number of beds 900. Salary £500 per annum. The candidate appointed will be required to reside in the Hospital and to pay for board, lodging, and washing at the rate fixed from time to time. At present the rate is £130 per annum. There is no accommodation for a married officer.

Application to be made not later than 10 a.m. on Saturday, June 8th, on form obtainable from the Clerk, Metropolitan Asylums Board, Victoria Embankment, London, E.C.4, by forwarding stamped addressed foolscap envelope.

ALLAN POWELL, Clerk to the Board.

Huntingdon County Hospital.

Male HOUSE SURGEON wanted at once. Salary at rate of £125 per annum, and washing. Applications, etc., to Senior Surgeon, County Hospital, Huntingdon.

Parish of Portsmouth.

THIRD ASSISTANT RESIDENT MEDICAL OFFICER.

The Guardians of the above-named Parish invite applications for the appointment of Third Assistant Resident Medical Officer for SAINT MARY'S HOSPITAL, INSTITUTION, AND CHILDREN'S HOME.

The appointment will be made for a period not exceeding two years, and will be subject to one month's notice on either side. Salary £250 per annum, with furnished apartments, rations, and all other allowances.

The appointment will be subject to the provisions of the Poor Law Officers Superannuation Act, 1896, for which purpose the value of the emoluments has been fixed at £125 per annum.

Candidates must be single gentlemen, duly registered, and possessing the qualifications required by the Orders of the Ministry of Health, and preference will be given to candidates having a knowledge of the treatment of Mental Diseases.

A Resident Medical Superintendent is in attendance.

Applications to be made on printed forms, which may be obtained at the Guardians' Offices, 1, St. Michael's Road, Portsmouth, and must be returned to me, accompanied by not more than three recent testimonials, and description of diplomas, certificates of degrees, licences, and other instruments held by the candidate, by 10 a.m. on Monday, June 17th.

Selected candidates will have notice to attend and third-class railway fare and reasonable personal expenses will be allowed.

By Order,
W. E. GODFREY,
May 27th, 1929. Clerk to the Guardians.

Carshalton Urban District Council.

MATERNITY AND CHILD WELFARE SERVICES.

MEDICAL OFFICER OF CLINICS.

The above Council invite applications from duly qualified medical practitioners (male or female) for the appointment of Medical Officer of Clinics.

Sessions are held at the Rochester Road Centre on Thursday afternoons weekly, and at Stanley Road Centre on Friday afternoons weekly. Ante-natal Clinics being held prior to the ordinary sessions.

The salary will be as follows:
Rochester Road Clinic—£100 per annum;
Stanley Road Clinic—30/- for each attendance; together with travelling expenses (to be fixed when the appointment is made).

The person appointed will be required to work under the general direction of the Medical Officer of Health for the District.

Applications, giving full details of qualifications and experience, accompanied by copies of not more than three recent testimonials, must be delivered to the undersigned not later than 12 noon on June 19th.

Canvassing, either directly or indirectly, will be deemed a disqualification.

By Order,
District Council Offices, J. WM. WRIGHT,
The Grove, Clerk to the Council.
Carshalton. May 28th, 1929.

Romford Union.

OLDCHURCH HOSPITAL.

RESIDENT THIRD ASSISTANT MEDICAL OFFICER.

The Guardians of the Romford Union invite applications for the appointment of a Third Assistant Resident Medical Officer (male) at their Oldchurch Hospital, Romford, which has a present accommodation of 550 beds. The Hospital is situated 12 miles from London.

Applicants must be single, and preference will be given to one who has held the position of House Surgeon or House Physician in a General Hospital.

The appointment is governed by the regulations laid down in the Orders of the Ministry of Health.

The salary will be at the rate of £250 per annum, subject to deductions under the Poor Law Officers Superannuation Act, 1896, with furnished apartments, maid, rations, and laundry.

Forms of application may be obtained from the undersigned upon receipt of a stamped addressed foolscap envelope, and must be returned not later than Monday, June 10th.

By Order,
Union Offices, R. H. MASON,
Romford. Clerk to the Guardians.
May 23rd, 1929.

Administrative County of Essex.

APPOINTMENT OF MALE ASSISTANT COUNTY MEDICAL OFFICER OF HEALTH.

The County Council of the Administrative County of Essex invite applications for the above post from registered medical practitioners specially qualified in the treatment of Tuberculosis, School Medical Inspection, and Maternity and Child Welfare, holding a Diploma of Public Health, and not over 45 years of age.

Preference will be given to candidates who have had at least three years' experience in Public Health work subsequent to their medical qualification. The salary attached to the appointment will be £600 per annum and travelling expenses. The person appointed will be required to devote his whole time to the service of the Council, and to perform such duties and to furnish such advice and assistance appertaining to his office as may be required, and to reside in such district of the County as the Council may decide. The appointment will be subject to three months' notice on either side.

Applications on the prescribed form, obtainable from the undersigned, and accompanied by copies of not more than three testimonials, which will not be returned, should be addressed to me and delivered at the Shire Hall, Chelmsford, not later than 10 a.m. on Monday, June 10th.

Shire Hall, JOHN H. GOOLD,
Chelmsford, Clerk of the County
May 24th, 1929. Council.

Urban District Council of Barking Town.

ASSISTANT MEDICAL OFFICER.

Applications are invited from qualified medical practitioners (preferably women) for the combined appointment of Assistant Medical Officer of Health and Assistant School Medical Officer under the Public Health and Education Committees of the above Council. The officer appointed will be required to devote his or her whole time to official duties and to reside within the district. The principal duties will consist of maternity and child welfare and school clinic work and the medical inspection of school children, to be carried out under the direction of the Medical Officer of Health, who is also the School Medical Officer. The appointment will be subject to one month's notice on either side. Salary £500 per annum, inclusive of all bonus, rising after one year's satisfactory service to £600 per annum.

The person appointed will be required to pass a medical examination and to contribute to the Council's Superannuation Fund.

Forms of application may be obtained from the undersigned, to whom they should be returned, endorsed "Assistant M.O.H.," with copies of not more than three recent testimonials, not later than June 7th.

Public Offices, H. HARGREAVES,
Barking. Clerk to the Council.
May 17th, 1929.

County Borough of Wolverhampton.

VISITING SURGEON.

The Wolverhampton Corporation propose to appoint a GENERAL OPERATING SURGEON, practising exclusively as such, for the Borough Infectious Hospital.

The gentleman appointed will be required to carry out all surgical work, consultative and operative, for which his services may be requested.

A retaining fee of 25 guineas per annum is offered, together with special fees for all operations performed by him.

As the scheme is experimental the appointment will be for one year only, and at the end of that period the position will be reviewed.

Any further details will be furnished on request.

Applications, endorsed "Visiting Surgeon," should be forwarded to the undersigned not later than June 12th.

Town Hall, J. BROCK ALLON,
Wolverhampton. Town Clerk.
May 30th, 1929.

King Edward VII Hospital,

Rivelin Valley Road, SHEFFIELD.
(Surgical Tuberculosis.) (130 Beds.)

HOUSE SURGEON (Resident).

Applications are invited for the above post, which falls vacant on July 1st. The appointment is for six months, with possible extension for a further six months. Salary £75 p.a., with board, residence, and laundry.

Applications and testimonials should be sent as soon as possible to the Medical Superintendent, King Edward VII Hospital, Rivelin Valley Road, Sheffield.

WEST AFRICAN MEDICAL STAFF

VACANCIES exist for MEDICAL OFFICERS and MEDICAL OFFICERS OF HEALTH in the BRITISH WEST AFRICAN COLONIES.

SALARIES.

Medical Officers receive salaries at the rate of £660 a year, rising by annual increments of £30 to £720 a year, and then on confirmation £720 a year, rising by annual increments of £40 to £960 a year, together with a seniority allowance (payable only in West Africa) at the rate of £72 a year. After three years' service on £960, the salary may be raised to the scale of £1,000 a year, rising by annual increments of £50 to £1,150 a year, together with a seniority allowance at the rate of £100 a year.

Medical Officers of Health receive salary on the above scale beginning at £800 a year, together with seniority allowance of £72 a year. They also draw staff pay at the rate of £150 a year, half of which is payable during leave.

QUARTERS.

Free furnished quarters are provided or an allowance in lieu.

OUTFIT ALLOWANCE.

An outfit allowance of £60 is granted on first appointment.

PASSAGES.

Free first-class passages are provided on first appointment, and when proceeding on or returning from leave.

PENSIONS.

All appointments are pensionable; a minimum service of seven years is required to qualify for a pension. An officer may retire on reaching the age of 50 and may be called upon to retire at the age of 55. Officers of the West African Medical Staff are permitted to retire if they wish with a gratuity of £1,000 or £1,250 after nine or twelve years' approved service respectively, but in that event they receive no pension.

TOURS OF SERVICE AND LEAVE.

A tour of service in West Africa lasts from twelve to eighteen months at the discretion of the Colonial Government, and is followed by leave at the rate of one week for each completed month of residential service. Leave begins on the date of arrival in England.

PROMOTION.

There are good prospects of promotion in the West African Medical Staff.

COURSE OF INSTRUCTION.

Selected candidates are required to attend courses of instruction in tropical medicine and hygiene at either the London School of Hygiene and Tropical Medicine or the Liverpool School of Tropical Medicine or the University of Edinburgh.

Further information regarding the conditions of service, pensions, etc., may be obtained from the Private Secretary (Appointments), Colonial Office, 2, Richmond Terrace, Whitehall, London, S.W.1, to whom applications should also be addressed.

Chesterfield and North-Derbyshire Royal Hospital.
(190 Surgical and Medical Beds.)

CASUALTY OFFICER AND HOUSE SURGEON TO EAR, NOSE, AND THROAT DEPARTMENT.

Applications are invited from fully qualified men for the above post.

Candidates must have held at least one previous Hospital appointment of six months. The selected candidate will act as deputy to the Resident Surgical Officer. The Resident Staff number five.

The appointment is for a period of six months. Salary at the rate of £200 per annum, with board, apartments, and laundry.

Applications, stating age, and when at liberty, with copies of three recent testimonials, should be sent to the undersigned on or before Tuesday, June 4th.

G. SUNNUCK,
May 27th, 1929. Supt. & Secretary.

Great Ormond Street, London, W.C.1.

A HOUSE SURGEON and a HOUSE PHYSICIAN are required on July 1st.

Gentlemen are invited to send in their applications, addressed to the Secretary, before 12 o'clock on Monday, June 3rd, with copies of not more than three testimonials given specially for the purpose, and also evidence of their having held a responsible Hospital appointment.

The appointments are made for six months. Salaries at the rate of £100 per annum, laundry allowance £5, board and residence in the Hospital.

Candidates must be unmarried and possess a legal qualification to practise.

All candidates must be in attendance to appear before the Joint Committee, if required, at their Meeting on Wednesday, June 5th, at 4.45 p.m. precisely.

Forms of application and copies of the rules may be obtained from the Secretary.

By Order of the Board of Management,
JAMES McKAY,
May, 1929. Secretary.

Hertford County Hospital.

Applications are invited for the post of HOUSE PHYSICIAN (male). Duties commencing June 17th. Salary £150 per annum, with board, residence, and laundry. Some knowledge of Pathology desirable. The appointment is for six months in the first instance.

Applications, with copies of three recent testimonials, should be sent to the undersigned and be received not later than June 8th.

PERCY G. BROOKS, Secretary.

London Skin Hospital.

HONORARY DERMATOLOGIST.

[illegible] for the above
[illegible]ted to forward
[illegible]nd experience,
[illegible] to the Hon.
[illegible], 40, Fitzroy
Square, W.1.

Under the personal direction of Dr. J. FIELD HALL and Mr. J. C. NEEDES

who have both had many years' experience as Medical Transfer Agents.

The commission chargeable in respect of any practice or partnership in Great Britain placed exclusively in the hands of this Agency has been fixed on an exceptionally favourable scale, the maximum chargeable on any transfer being fifty pounds (£50).

No charge is made to Principals for the introduction of Locum Tenens or Assistants.
Accountancy and legal services furnished by the Agency, where desired, at moderate inclusive charges.

1. NORTH-EAST COAST.—Favourite Seaside Resort.—PARTNERSHIP. A share representing about £1,400 p.a. is for disposal in an exceptionally sound middle and better-class Practice, with increase later. Selected panel of 750. Visits 5/- to 10/6, with mileage extra. Midwifery 3 to 7½ gns.; about 40 cases. Suitable house available. Premium 2 years' purchase. Ingoing partner should be about 30, and have held Hospital appointments.
2. PARTNERSHIP.—SOUTH-WESTERN COUNTY.—In a large seaport town the THIRD SHARE (to commence with) of an old-established mixed-class Practice averaging £3,200 p.a., including panel of over 2,000, is offered. Visits 3/6 to 10/6. Midwifery discouraged; about 30 cases yearly at 3 gns. upwards. Expenses light. Suitable residence available. Premium 2 years' purchase.
3. EAST COAST.—ASSISTANTSHIP with view to PARTNERSHIP.—A one-third share in a very sound mixed-class Practice, producing £2,500 p.a., and offering excellent scope. Panel of about 1,000, and good appointments. Choice of houses. Premium 2 years' purchase.
4. SUSSEX.—PARTNERSHIP.—A one-half share in a very old-established unopposed Practice in delightful district near sea. Average cash receipts for past three years £2,800, including £1,000 from panel and appointments. Visits 3/6 to 42/-. Midwifery from 2 gns.; about 30 cases. Very attractive house, with 2 reception, 5 bedrooms, etc., large garden. Can be rented on lease at £80 p.a. Excellent sport and schools. Premium 2 years' purchase.
5. WITHIN FIFTEEN MILES OF LONDON.—PARTNERSHIP.—A three-eighths share, with increase later, is offered in a well-established Practice in favourite residential district. Receipts average about £3,000 p.a., including panel of 1,500. Fees 3/6 to 21/-. Choice of two houses. Good society, sport, and schools. Cottage Hospital and excellent scope for surgery. Premium 2 years' purchase, part by instalments.
6. MANCHESTER.—PRACTICE is situated in a growing district offering very good scope. Income for the immediate past 12 months over £1,600, including panel of nearly 900. Fees 3/6 upwards. Detached well-situated house, with 3 reception, 5 bedrooms, etc. Can be rented on lease at £110 p.a. Premium 1½ years' purchase.
7. LONDON.—E[illegible]h and panel PRACTICE producing £450 patients. Visits 3/- upwards. Very little house on lease. Rent £78, inclusive of £650.
8. WITHIN 50 MILES OF LONDON.—In a small Country Town, in pretty district, a well-established increasing PRACTICE, worth last year over £800, including panel of 525, and appts. about £60. Visits 3/6 to 21/-, medicine extra. Midwifery discouraged. Railway station in place. Very good house (3 reception, 5 bedrooms, etc.), with large garden. Tennis court. Garage. Electric light. Price for freehold £3,100. Premium 1½ years' purchase. Exceptionally good educational facilities for boys.
9. WORCS.—COUNTRY PRACTICE, near large town.—Very old-established good mixed Practice in attractive district. Average income for past three years £1,027, including panel of 560, and appts. worth over £60 p.a. Fees 2/6 to 10/-. About 30 cases of midwifery 2 and 3 gns. House is very well situated, and contains 2 reception, 5 bedrooms, etc., and separate professional rooms. Good garden. Garage for 2 cars. Price for freehold £2,000, half on mortgage. Excellent sport. Premium £1,350.
10. CARDIFF. — Good-class old-established non-dispensing PRACTICE, worth last year about £1,350, including select panel of 450. Visits up to 21/-. Very little midwifery. Good house in best part of City, with ample accommodation. Price, freehold, £2,000. Prem. £2,000.
11. PLYMOUTH.—Old-established and increasing mixed-class PRACTICE, worth last year nearly £2,000 (at rate of £3,000 for first 3¼ months of this year), including appts. worth £140 and panel of 1,100. Visits 3/6 to 21/-. Midwifery 3 to 5 gns. (60 to 80 cases yearly. Convenient house (professional accommodation, 2 reception, 4 bedrooms, etc.) on long lease at £80 a year. Premium £3,000. Efficient introduction given
12. WITHIN 60 MILES OF LONDON.—Unopposed very old-established easily worked PRACTICE, in pretty country district about 5 miles from Hospital Town Cash receipts last financial year £1,552 (shows considerable increase for last 9 months), including appts. and panel (nearly 1,200) £899. Visits 3/6 to 10/6, medicine extra. Practically no midwifery. Excellent modern freehold residence (bathroom, electric light, system drainage, etc.), with ample accommodation. Garden. Garage. Price £3,300, £2,300 can remain on mortgage. Premium £2,400, to include drugs, etc. Good hunting, shooting.
13. FAVOURITE INLAND SPA.—PARTNERSHIP.—A well-qualified experienced gentleman (aged about 40, married, and good at Gynæcology) is required to purchase the half share of an old-established good-class non-dispensing Practice owing to the retirement through ill health of the senior partner. Income about £5,000, including small select panel. Good number of midwiferies. Suitable house available, with ample accommodation, at low rental. Premium 2 years' purchase.
14. SOUTH LONDON (NEAR CROYDON).—Sound and increasing mixed-class PRACTICE, in growing locality. Gross cash receipts for immediate past 12 months £2,800, including panel of 2,240. Fees 2/6 to 7/6. Convenient freehold house, with electric light. Garage. Garden. Good sport and schools. Premium £4,500. Efficient introd.
15. PARTNERSHIP, with ultimate succession.—SOUTH-WEST LONDON.—A third or half share, to commence with, in an old-established good mixed non-panel Practice, offering large scope. Receipts for last year nearly £2,300. Fees 2/6 to 7/6. Little midwifery. Good house, with garden. Can be obtained on long lease at the very moderate rent of £55 p.a. Premium 2 years' purchase.
16. MIDLANDS.—Country district, near large Town.—Agricultural and working-class PRACTICE, rapidly increasing. Income last year £1,250, including panel of 545. Visits 3/6 and 5/-. Small convenient house, freehold. Price, including all furniture, excepting linen and plate, £1,650 (£1,000 on mortgage at 4 per cent.). Large garden. Garage. Excellent sport. Premium £1,800.
17. LANCS.—COAST TOWN.—Old-established better and middle-class PRACTICE. Income for 1928 over £1,200. Panel of 556. Visits from 4/-. Well situated house in residential district. Price for freehold £2,700, £1,500 on mortgage. Premium £1,800, £1,000 down and balance by instalments.
18. NEW ZEALAND.—(North Island).—In an up-to-date Town (pop. 12,000, with a further 10,000 in outlying district) within 12 miles of the sea, a well-established PRACTICE worth last year over £1,000, including appts. averaging £280. Visits 10/6 to 21/-, mileage extra. No dispensing. Excellent Bungalow residence, in an acre of garden, with fruit trees, tennis court, etc., containing 9 rooms, bathroom, etc. Electric light, h. and c. water. Climate finest in New Zealand. Splendid educational facilities and unlimited sport. Scope for surgery.
19. PARTNERSHIP.—LONDON.—In a populous district, the half share of an old-established middle and working-class Practice, worth over £2,000 p.a., including panel of 1,300. Visits 3/6 to 10/6. Expenses light, car not necessary. House contains professional accommodation, 2 reception, 2 bedrooms, bathroom, etc. Held on lease at rental of about £60 p.a. Premium 2 years' purchase.
20. PARTNERSHIP.—OUTLYING WESTERN SUBURB.—A one-third or one-half share is for disposal in a well-established mainly better working-class Practice, producing over £2,300 p.a. Appointments worth about £100 p.a., and panel of 1,400. Fees from 2/6 to 21/-. Lowest midwifery 3 gns. Purchaser (if single) could reside in rooms, or suitable house obtainable. Premium 2 years' purchase.
21. SHEFFIELD.—Good-class non-panel non-dispensing PRACTICE in best residential district. Average income for last three years over £3,000. Fees 5/- to 21/-. Midwifery 3 to 10 gns., about 30 cases yearly. Surgery premises can be rented on lease, and contain consulting room, waiting room, 3 bedrooms. Electric light. Garden. Purchaser can choose his own place of residence. Premium 1½ years' purchase, with 1 or 2 years' partnership introduction as required.
22. STAFFS.—LARGE TOWN.—Owing to ill health of present Incumbent, an old-established good-class non-panel non-dispensing PRACTICE is for immediate disposal. Income last year over £1,200. Fees 5/- to 10/-. Commodious house, in best residential road. Price for freehold £1,600, part on mortgage. Prem. £1,500, payable easy instalments.
23. SOUTH-WEST OF ENGLAND.—Large Thriving Hospital Town.—PARTNERSHIP.—The half or five-ninths share in an old-established better and middle-class non-panel general and surgical Practice can be acquired by a suitable gentleman possessing the F.R.C.S. degree. Receipts for the past three years average over £5,000 p.a. Good house, with ample accommodation, at present held on lease with option to purchase. Premium 2 years' purchase.
24. BORDERS OF NORFOLK AND SUFFOLK. — Very old-estab. good middle-class PRACTICE, averaging over £1,000 p.a., including panel of 530. Visits from 3/6. Easily worked. Very attractive house, modernized, and containing 3 reception, 6 bedrooms, bathroom (h. and c.), separate professional accommodation. Price for freehold £2,000. Premium £1,500.
25. BORDERS OF CORNWALL AND DEVON.—PARTNERSHIP.—A half-share is offered in a very sound mixed-class Practice, situated in delightful district, near coast. Gross cash receipts upwards of £2,900, including panel of over 1,200, and good appts. Low expenses. Convenient house, with 3 reception, 4 bedrooms, and usual offices. Garden. Price £750, part on mortgage. Premium 2 years' purchase.
26. DEATH VACANCY. — NORTH DEVON. — UNOPPOSED COUNTRY PRACTICE in delightful district. Very old-established mixed general Practice held by the late Incumbent for the past 16 years. Income for 1928 £1,266, including panel of approximately 700. Exceptionally good house, standing in 2 acres of garden, with 2 reception, 6 bedrooms, etc., surgery and waiting room. Electric light. Garage for two cars. Premium for Practice and house £4,000.
27. GLOUCESTERSHIRE — Very old-established unopposed Country PRACTICE, held by Vendor for the past ten years, and situated in attractive district, near good town. Cash receipts for 1928, £455, and this year at the rate of £700. Panel of over 500. Fees 2/6 to 12/6. Commodious house, with 6 bedrooms, etc. One acre of garden and paddock. Price for freehold £1,200. Premium £900.

Full Schedule of Terms and Conditions will be forwarded on application.

Valentine's Meat-Juice

In **Typhoid Fever, Diarrhoea and Cholera Infantum,** when it is **Essential** to **Sustain** the patient **without irritating** the **Digestive Organs,** the **Ease** of **Assimilation** and **Power** of **Valentine's Meat-Juice** to **Restore** and **Strengthen** has been demonstrated in Hospital and Private Practice.

THE quickness and power with which VALENTINE'S MEAT-JUICE acts, the manner in which it adapts itself to and quiets the irritable stomach, its agreeable taste, ease of administration and entire assimilation recommend it to physician and patient.

Physicians are invited to send for brochures containing clinical reports.

For sale by European and American Chemists and Druggists.

VALENTINE'S MEAT-JUICE COMPANY,

Richmond, Virginia, U. S. A.

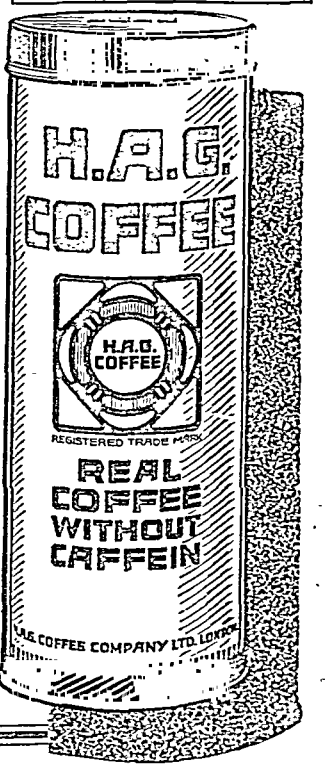
THE injurious action of caffein, to which the ailing, reconvalescents and those in good health become liable by the habitual or excessive consumption of coffee and tea, is causing an increased interest in the medical world. There is already a comprehensive literature dealing with this subject; in many cases it absolutely bans the consumption of beverages containing caffein.

THE physician who is solicitous with regard to the welfare and ailments of his patients will specially value the knowledge that **H.A.G. COFFEE**—a caffein-free berry coffee—is obtainable, which in respect to aroma and palatableness, affords the same sense of enjoyment as ordinary coffee containing caffein, but without its harmful action on the cardiac, the nervous, and the vascular system.

WITH **H.A.G. COFFEE** the caffein is extracted from the unroasted coffee bean by a patented process, until only a slight, non-effective trace remains. Previous to this treatment, the coffee beans undergo a most thorough cleansing.

CAFFEIN-free **H. A. G. COFFEE** can confidently be recommended as the best and most valuable health coffee, and, in order to give members of the Medical Profession an opportunity of personally appreciating the hygienic characteristics of **H.A.G. COFFEE,** we shall be pleased to send a sample and literature free on request.

H.A.G. Coffee can be obtained in 2 sizes, price 3/2 and 1/8, either ground or in the bean. If your grocer has no stock we will supply post free upon receipt of your remittance



H.A.G. COFFEE CO. LTD.

HORMOTONE
for
PREMATURE SENILITY
and
OLD AGE

Stimulates metabolism
Increases muscle tonicity
Raises respiratory exchange
Effects marked subjective improvement

"Old age being caused by degeneration of the endocrine glands, especially the thyroid and sexual glands, all that is necessary to secure rejuvenation is to improve the condition of these glands. The best and easiest way to do this is to administer by the mouth extracts of these glands, after their extirpation from healthy animals. . . .

"The persons treated looked considerably younger after it, to the extent of ten or fifteen years, and sometimes even more. The wrinkles in the face already began to disappear four or five weeks after the treatment, and, at the same time, previously corpulent persons, losing their excess of fat, were made to look slender, thus imparting a youthful impression."

(Lorand, "Life Shortening Habits and Rejuvenation," 1922.)

JUST ISSUED

GRANGER'S

JUST ISSUED

Physical Therapeutic Technique

Dr. Granger has written a book that deals entirely with the practical application of all types of physical procedure in the treatment of disease. As expressed in the preface, the material presented is for the general practitioner—the doctor who owns a limited equipment—in order to enable him to do more and better work with that equipment.

The book is complete, presenting all those diseases in which the author, in his twenty-five years of practice in the field of physical therapeutics, has found these procedures of real practical value. It states definitely the degree of success which may reasonably be expected in each disease discussed, thus making the work of great value to all physicians.

By FRANK B. GRANGER, A.B., M.D., Late Physician-in-Chief, Department of Physical Therapeutics, Boston City Hospital, etc. With a Foreword by WILLIAM D. McFEE, M.D. Octavo of 417 pages, illustrated. Cloth, 30s. net.

In Three Volumes

BLUMER'S BEDSIDE DIAGNOSIS

Just Issued

Edited by GEORGE BLUMER, M.D., David P. Smith Clinical Professor of Medicine, Yale University Medical School. Three octavo volumes, totalling 2,820 pages, with 890 illustrations. *Per set, Cloth,* £6 15s. net. Index volume free.

"... the book is well bound, the print is excellent, and the illustrations carefully chosen and well reproduced. Not only is each volume indexed but a separately bound index to the whole three volumes is provided, so that fruitless searching in the wrong volume can be avoided. The physician will find it hard to get a finer book."—THE LANCET.

New (3rd) Edition

NEOPLASTIC DISEASES

New (3rd) Edition

By JAMES EWING, Sc.D., M.D., Professor of Pathology, Cornell University Medical School. Octavo of 1,127 pages, with 546 illustrations. Cloth, 63s. net.

"It would be strange to come across any pathological laboratory where this book did not show the signs of frequent consultation. To the surgeon it is a necessity if he would seek to be more than a mere operator. The specialist and the practitioner will find it a mine of useful information."—BRITISH MEDICAL JOURNAL.

Just Issued

EXAMINATION OF PATIENTS

New (2nd) Edition

By NELLIS B. FOSTER, M.D., Associate Professor of Medicine, Cornell University College of Medicine. Octavo of 392 pages, with 83 illustrations, a number in colours. Cloth, 21s. net.

"Dr. Foster here records his routine in the examination of patients, and the precision of his writing, the thoroughness of his method, and his critical but sympathetic attitude to recent advances make his book a most valuable one to all those engaged in general practice."—THE LANCET.

A New Work

GONORRHŒA IN THE MALE

Just Issued

By P. S. PELOUZE, M.D., Associate in Urology and Assistant Genito-Urinary Surgeon, University of Pennsylvania. Octavo of 351 pages, illustrated. Cloth, 24s. net.

"The keynote of this book is simplicity—simplicity in exposition and simplicity in treatment. . . . Dr. Pelouze's book should be read by every practitioner who intends to treat gonorrhœa."—BRITISH MEDICAL JOURNAL.

Just Issued

NUTRITION AND DIET

Just Issued

By JAMES McLESTER, M.D., Professor of Medicine at the University of Alabama. Octavo of 783 pages. Cloth, 36s. net.

"The book is characterized by a sane and well balanced outlook and a comprehensive and succinct treatment of the several aspects of dietetics."—BRITISH MEDICAL JOURNAL

CONSTABLE'S MEDICAL BOOKS

New Titles and Editions just Published

A TEXT-BOOK OF PULMONARY TUBERCULOSIS

By R. C. WINGFIELD, M.B., B.A.(Oxon.), F.R.C.P. Demy 8vo. Illustrated. 31s. 6d. net.

The subject of pulmonary tuberculosis is now receiving such official and general attention that it has become a speciality. Tuberculosis services have been formed, and in one University a Chair of Tuberculosis has been constituted. These facts alone justify the publication of a book of this size dealing exclusively with the subject. The majority of the works hitherto published are either too large and detailed for the student, or are too short and elementary. Dr. Wingfield has attempted to produce a book in between these two classes in the hope that it will form a complete account of the subject for medical students and practitioners who, during the course of their work, have to pay special attention, either through interest or possibly through a local appointment in town or borough, to the subject of tuberculosis.

This volume is the result of the Author's actual experience combined with his wide knowledge of its literature. It is not, therefore, a conglomerate résumé of other workers' opinions and publications, but a practical, well-balanced, consecutive survey of the disease.

HEART DISEASE IN CHILDHOOD *(Modern Medical Monograph)*

By H. B. RUSSELL, M.D., M.R.C.P., and C. K. J. HAMILTON, B.M., M.R.C.P. Demy 8vo. 7s. 6d. net.

The authors have treated their subject in a lucid and most able manner, discussing the problems with which every practitioner has to contend, and explaining methods of diagnosis and treatment.

FEEDING IN INFANCY AND CHILDHOOD *(Modern Medical Monograph)*

SECOND EDITION, REVISED.

By DONALD PATERSON, B.A., M.D., F.R.C.P., and J. FOREST SMITH, M.R.C.P. Demy 8vo. 7s. 6d. net.

Every practitioner is confronted at some time or another with the difficulty of feeding the infant which shows inability to take ordinary diet. This popular monograph is a complete and reliable guide to such problems.

"One of the great merits of the book lies in its recognition of the importance of providing practitioners with régimes *which are simple enough to be universally practicable.*"—LANCET.

STANDARD WORKS
